ABSTRACT. We study combinatorial and order theoretic structures arising from the fragment of combinatory logic spanned by the basic combinator M. This basic combinator, named as the Mockingbird by Smullyan, is defined by the rewrite rule $M x_1 \rightarrow x_1 x_1 x_1$. We prove that the reflexive and transitive closure of this rewrite relation is a partial order on terms on $M$ and that all connected components of its rewrite graph are Hasse diagram of lattices. This last result is based on the introduction of new lattices on duplicative forests, which are sorts of treelike structures. These lattices are not graded, not self-dual, and not semidistributive. We present some enumerative properties of these lattices like the enumeration of their elements, of the edges of their Hasse diagrams, and of their intervals. These results are derived from formal power series on terms and on duplicative forests endowed with particular operations.

INTRODUCTION

Combinatory logic is a model of computation introduced by Schönfinkel [Sch24] and developed by Curry [Cur30] with the objective to abstain from the need of bound variables specific to the $\lambda$-calculus. Its combinatorial heart is formed by terms, which are binary trees with labeled leaves, and rules to compute a result from a term, which are rewrite relations on trees [BN98,BKdVT03] (clear and complete modern references about combinatory logic are [HS08,Bim11]). An important instance of combinatory logic is the system containing the basic combinators $K$ and $S$ together with the two rewrite rules

\[
\begin{align*}
K x_1 x_2 & \rightarrow x_1 \\
S x_1 x_2 & \rightarrow x_1 x_3 \ x_2 \ x_3
\end{align*}
\quad (0.0.1)
\]

In this system, we have for instance the sequence of computation

\[
\begin{array}{c}
S \ K \ K \ S \ \Rightarrow \ K \ S \ S \ \Rightarrow \ S \ K \ S \ S \ \Rightarrow \ S \ S \ S
\end{array}
\quad (0.0.2)
\]

obtained by performing at each step one rewrite according to the previous rules. This system is important because it is combinatorially complete: each $\lambda$-term can be translated, by so-called bracket abstraction algorithms [Sch24,CF58], into a term over $K$ and $S$ emulating it.

A lot of other basic combinators with their own rewrite rules have been introduced by Smullyan in [Smu85] after —now widely used— bird names, forming the enchanted forest of combinator birds. For instance, $K$ is the Kestrel and $S$ is the Starling. Usual computer science oriented questions consist in considering a fragment of combinatory logic, that is a finite set of combinators with their rewrite rules which is not necessarily combinatorially complete, and ask for the following questions:

(a) Given two terms $t$ and $t'$, can we decide if $t$ and $t'$ can be rewritten eventually in a same term? This is known as the word problem [BN98,Sta00]. This question admits a positive answer for some basic combinators like among others the Lark [Sta89,SWB93] and the Warbler [SWB93] but it still open for the Starling [BEKW17];

(b) Given a term $t$, can we decide if all rewrite sequences starting from $t$ are finite? This is known as the strong normalization problem. This question admits a positive answer for, among others, the Starling [Wal00] and the Jay [PS01]. Related to this, see also [DGK+13,BGZ17] for a probabilistic and asymptotic study of strong normalizing terms.

Here, we decide to pursue this study in a different direction by asking questions from a combinatorial point of view, including the study of order theoretic structures and adopting an enumerative approach. In particular, by denoting by $\preceq$ (resp. by $\equiv$) the reflexive and transitive (resp. reflexive, symmetric, and transitive) closure of the rewrite relation, we ask the following questions:

(a) Given two terms $t$ and $t'$, can we decide if $t$ and $t'$ are eventually in the same equivalence class? This is known as the equivalence problem [BN98,Sta00]. This question admits a positive answer for some basic combinators like among others the Lark [Sta89,SWB93] and the Warbler [SWB93] but it still open for the Starling [BEKW17];

(b) Given a term $t$, can we decide if all equivalence classes starting from $t$ are finite? This is known as the strong equivalence problem. This question admits a positive answer for, among others, the Starling [Wal00] and the Jay [PS01]. Related to this, see also [DGK+13,BGZ17] for a probabilistic and asymptotic study of strong normalizing terms.
(a') Determine if $\preceq$ is a partial order relation;
(b') In this case, determine if each interval of this poset is a lattice;
(c') Enumerate the $\equiv$-equivalence classes of terms w.r.t. the minimal degrees of their terms.

This work fits in this general project consisting in mixing combinatory logic with combinatorics.

We choose here to start this project by studying the system made of a single combinator, the combinator $\mathbf{M}$, known as the Mockingbird [Smu85 or as the little omega. This combinator is a very simple and an important one (see for instance [Sta11b, Sta17]). By drawing the portions of the rewrite graph starting from terms on $\mathbf{M}$, the first properties that stand out are that the graph does not contain any nontrivial loops and that its connected components are finite and have exactly one minimal and one maximal element. At this stage, driven by computer exploration, we conjecture that the relation $\preceq$ on the terms on $\mathbf{M}$ is a partial order relation and that each $\equiv$-equivalence class is a lattice w.r.t. this partial order relation. This lattice property is for us a good clue for the fact that this system contains rather rich combinatorial properties.

To prove this last property, we introduce new lattices on duplicative forests, that are kinds of treelike structures, and show that each maximal interval from any term on $\mathbf{M}$ is isomorphic as a poset to a maximal interval of a lattice of duplicative forests (Theorem 2.3.4). We define the Mockingbird lattice of order $d \geq 0$ as the lattice $\mathbf{M}(d)$ consisting in the closed terms on $\mathbf{M}$ equal as or greater than the right comb closed term on $\mathbf{M}$ of degree $d$. We prove that each interval of the poset of duplicative forests is contained as an interval in $\mathbf{M}(d)$ for a certain $d \geq 0$ (Theorem 2.3.5). Since any closed term on $\mathbf{M}$ can be seen as a binary tree, this provides a new lattice structure on these objects. A lot of similar lattices have been studied on binary trees such as, among others the very famous Tamari lattice [Tam62], the Kreweras lattice [Kre72], the Stanley lattice [Sta75], the phagocyte lattice [BP06], and the pruning-grafting lattice [BP08]. However, unlike these lattices having for each order $d \geq 0$ a cardinality equal to the $d$-th Catalan number, the lattices $\mathbf{M}(d)$ are enumerated by a different integer sequence. To obtain enumerative results about the Mockingbird lattices and all the posets of terms on $\mathbf{M}$ in general, we use formal power series on terms and on duplicative forests, and several products on these. In this way, we enumerate the minimal and maximal elements of the infinite poset of the closed terms on $\mathbf{M}$ (Propositions 3.2.1 and 3.2.2), the lengths of the shortest and longest saturated chains of $\mathbf{M}(d)$ (Proposition 3.3.1), the cardinality of $\mathbf{M}(d)$ (Proposition 3.4.3), the number of edges of the Hasse diagram of $\mathbf{M}(d)$ (Proposition 3.4.6), and the number of intervals of $\mathbf{M}(d)$ (Proposition 3.4.10). We also provide general results for systems of combinatory logic: we give in particular a necessary condition on the rewrite rules in order to have only finite connected components in the rewrite graph (Proposition 1.2.3). This relies on a combinatorial property on basic combinators, called the hierarchical property. We also discuss some consequences of this fact in order to construct models for systems having this property. These are in fact the algebras over a certain abstract clone [Tay93] defined from the system. When the relation $\preceq$ is a partial order relation, such models have a potential nice algorithmic computational complexity.

This paper is organized as follows. Section 1 contains the preliminary notions and definitions about terms, rewrite relations, and combinatory logic systems. We show here some general properties of these systems. In Section 2, we study the combinatory logic system on $\mathbf{M}$ and the Mockingbird lattices. Finally, Section 3 contains our enumerative results about
Mockingbird lattices. This text ends with the presentation of some open questions raised by this work.

This paper is an extended version of [Gir22] containing the proofs of the presented results and presenting new ones as discussions about some models of the combinatory logic system on $M$ and the enumeration of isolated elements of the poset of the closed terms on $M$.

General notations and conventions. If $S$ is a finite set $\#S$ is the cardinality of $S$. For any integers $i$ and $j$, $[i, j]$ denotes the set $\{i, i + 1, \ldots, j\}$. For any integer $i$, $[i]$ denotes the set $[1, i]$ and $[i]$ denotes the set $[0, i]$. For any set $A$, $A^*$ is the set of all words on $A$. For any $w \in A^*$, $\ell(w)$ is the length of $w$, for any $i \in [\ell(w)]$, $w(i)$ is the $i$-th letter of $w$, and $|w|_a$ is the number of occurrences of the letter $a \in A$ in $w$. The only word of length 0 is the empty word $\epsilon$. For any statement $P$, the Iverson bracket $[P]$ takes 1 as value if $P$ is true and 0 otherwise.

1. Terms, rewrite relations, and combinatory logic systems

In this preliminary part, we set the main definitions and notations used in the sequel. We introduce also the central notion of combinatory logic systems, which are defined from special kinds of rewrite relations. We show also some general properties of these systems.

1.1. Terms, compositions, and rewrite relations. Let us start by presenting here the notions of terms, composition, and rewrite relations.

1.1.1. Terms. An alphabet is a finite set $\mathcal{S}$. Its elements are called constants or basic combinators. Any element of the set $X := \bigcup_{n \geq 1} X_n$, where $X_n := \{x_1, \ldots, x_n\}$, is a variable. The set $\mathcal{T}(\mathcal{S})$ of $\mathcal{S}$-terms (or simply terms when the context is clear) is so that any variable of $X$ is a $\mathcal{S}$-term, any constant of $\mathcal{S}$ is a $\mathcal{S}$-term, and if $t_1$ and $t_2$ are two $\mathcal{S}$-terms, then $(t_1 \ast t_2)$ is a $\mathcal{S}$-term.

From this definition, any term is a rooted planar binary tree where leaves are decorated by variables or by constants. We shall express terms concisely by removing superfluous parentheses by considering that $\ast$ associates to the left and also by removing the symbols $\ast$ (see the example given in (1.1.1), (1.1.2), and (1.1.3)). For any $n \geq 0$, we denote by $\mathcal{T}_n(\mathcal{S})$ the set of $\mathcal{S}$-terms $t$ having all variables belonging to $X_n$.

Let $t$ be a $\mathcal{S}$-term. The degree $\deg(t)$ of $t$ is the number of internal nodes (the nodes decorated by $\ast$) of $t$ seen as a binary tree. For any $a \in X \cup \mathcal{S}$, $\deg_a(t)$ is the number of nodes labeled by $a$ in $t$. The depth of a node $u$ of $t$ is the number of internal nodes in the path connecting the root of $t$ and $u$. The height $\text{ht}(t)$ of $t$ is the maximal depth among all the nodes of $t$. The frontier of $t$ is the sequence of all the variables appearing in $t$ from the left to the right. The term $t$ is planar if its frontier is of the form $x_1x_2\ldots x_n$ where $n \geq 0$. The term $t$ is linear if there are no multiple occurrences of the same variable in its frontier. A closed term or combinator is a term of $\mathcal{T}_0(\mathcal{S})$ having thus no occurrence of any variable.

For instance, by setting $\mathcal{S} := \{A, B\}$, the $\mathcal{S}$-term

$$t := (((A \ast x_3) \ast (B \ast (x_1 \ast (x_1 \ast x_3) \ast x_1))) \ast (A \ast A))$$

(1.1.1)
draws as the binary tree

\[ t = (A \times_3)(B(x_1x_3))((A A) \times_3). \]  

\[ (1.1.3) \]

Its degree is 7, its height is 5, its frontier is \( x_3x_1x_3x_1 \), and is an element \( \mathfrak{T}_n(\mathfrak{G}) \) for any \( n \geq 3 \).

1.1.2. **Compositions of terms and clones.** Let \( t \) and \( t'_1, \ldots, t'_n \), \( n \geq 0 \), be \( \mathfrak{G} \)-terms. The *composition* of \( t \) with \( t'_1, \ldots, t'_n \) is the \( \mathfrak{G} \)-term \( t[t'_1, \ldots, t'_n] \) obtained by simultaneously replacing for all \( i \in [n] \) all occurrences of the variables \( x_i \) in \( t \) by \( t'_i \). For instance

\[ A(x_3x_1)x_3[x_1x_4, x_1x_4x_2] A(A x_1) = A(A(A x_1))(x_1x_4)(A(A x_1)). \]  

\[ (1.1.4) \]

Given two \( \mathfrak{G} \)-terms \( t \) and \( s \), \( s \) is a *factor* of \( t \) if

\[ t = t'[s_1, \ldots, s_i, t_i, s_{i+1}, \ldots, s_n][r_1, \ldots, r_m] \]  

\[ (1.1.5) \]

for some integers \( n, m \geq 0 \) and \( \mathfrak{G} \)-terms \( t', s_i', t_{i-1}, \ldots, s_{n}, r_1, \ldots, r_m \), where \( x_i \) appears in \( t' \). When this property does not hold, \( t \) *avoids* \( s \). When in \( (1.1.5) \), for all \( i \in [m] \) the \( r_i \) are variables, \( s \) is a *suffix* of \( t \). When this property does not hold, \( t \) *suffix-avoids* \( s \). For instance, the term defined in \( (1.1.3) \) admits \( B(x_1x_2) \) as factor, \( x_1x_2x_3 \) as suffix, but suffix-avoids \( x_1x_1x_1 \).

Observe that we have, for any \( n, m \geq 0 \), \( i \in [n] \), and \( t, s_i, \ldots, s_n, r_1, \ldots, r_m \in \mathfrak{T}(\mathfrak{G}) \),

\[ x_i[t_1, \ldots, t_n] = t_i, \]  

\[ (1.1.6a) \]

\[ t[x_1, \ldots, x_n] = t, \]  

\[ (1.1.6b) \]

\[ t[s_1, \ldots, s_n][r_1, \ldots, r_m] = t[s_1[r_1, \ldots, r_m], \ldots, s_n[r_1, \ldots, r_m]]. \]  

\[ (1.1.6c) \]

These three relations imply that the set \( \mathfrak{T}(\mathfrak{G}) \) together with the composition operation is an abstract clone [Tay93]. This is in fact the free abstract clone generated by \( \mathfrak{G} \cup \{*\} \) where \(*\) is a binary generator.

1.1.3. **Rewrite relations.** A *rewrite relation* on \( \mathfrak{T}(\mathfrak{G}) \) is a binary relation \( \Rightarrow \) on \( \mathfrak{T}(\mathfrak{G}) \). The *context closure* of \( \Rightarrow \) is the binary relation \( \Rightarrow \) on \( \mathfrak{T}(\mathfrak{G}) \) satisfying

\[ t[s_1, \ldots, s_n][r_1, \ldots, r_m] \Rightarrow t[s'_1, \ldots, s'_n][r_1, \ldots, r_m] \]  

\[ (1.1.7) \]

where \( t \) is a planar \( \mathfrak{G} \)-term, \( s_1, \ldots, s_n, s', n \geq 1 \), \( i \in [n] \), and \( r_1, \ldots, r_m, m \geq 0 \), are \( \mathfrak{G} \)-terms, and \( s_i \rightarrow s'_i \). Intuitively, \( t \Rightarrow t' \) if \( t' \) can be obtained from \( t \) by replacing a factor \( s \) of \( t \) by \( s' \) and by identifying variables with terms in a coherent way, whenever \( s \rightarrow s' \). For instance, for \( \mathfrak{G} := \{A, B, C\} \) and the rewrite relation \( \Rightarrow \) satisfying \( x_1(A x_1) \rightarrow x_1x_2 \), we have

\[ x_3B(A(x_3B))(x_4A) \Rightarrow x_3B C(x_4A). \]  

\[ (1.1.8) \]

because

\[ x_3B(A(x_3B))(x_4A) = x_1(x_2A) x_1[x_1(A x_1), x_4] [x_3B, C, x_3, x_4] \]  

\[ (1.1.9) \]

and

\[ x_3B C(x_4A) = x_1(x_2A) [x_1x_2, x_4] [x_3B, C, x_3, x_4]. \]  

\[ (1.1.10) \]
Observe in this example that the variable \( x_2 \) occurs in the right member of \( \rightarrow \) and not in the left member. For this reason, this variable can be replaced by any term in the context closure of \( \rightarrow \) (it is replaced by \( C \) in the example).

1.1.4. Applicative term rewrite systems. An applicative term rewrite system (or ATRS for short) is a pair \( (\mathcal{E}, \rightarrow) \) such that \( \mathcal{E} \) is an alphabet and \( \rightarrow \) is a rewrite relation on \( \mathcal{T}(\mathcal{E}) \). Let \( \mathcal{T} := (\mathcal{E}, \rightarrow) \) be an ATRS. We denote by \( \preceq \) the reflexive and transitive closure of \( \Rightarrow \). This relation \( \preceq \) is by construction a preorder. We denote by \( = \) the reflexive, symmetric, and transitive closure of \( \Rightarrow \) and by \([t]_\equiv \) the \( = \) equivalence class of \( t \in \mathcal{T}(\mathcal{E}) \). This relation \( = \) is by construction an equivalence relation. The rewrite graph \( G_\mathcal{T} \) of \( \mathcal{T} \) is the digraph on the set \( \mathcal{T}(\mathcal{E}) \) of vertices where there is an arc from \( t \in \mathcal{T}(\mathcal{E}) \) to \( t' \in \mathcal{T}(\mathcal{E}) \) if \( t \Rightarrow t' \). For any \( t \in \mathcal{T}(\mathcal{E}) \), we also denote by \( G_\mathcal{T}(t) \) the subgraph of \( G_\mathcal{T} \) restrained on the set \( \{ t' \in \mathcal{T}(\mathcal{E}) : t \preceq t' \} \) of vertices.

The ATRS \( \mathcal{T} \) is locally finite if for any term \( t \), \([t]_\equiv \) is finite. This is equivalent to the fact that all the connected components of \( G_\mathcal{T} \) are finite. A \( \mathcal{E} \)-term \( t \) is a normal form of \( \mathcal{T} \) if there is no arc of source \( t \) in \( G_\mathcal{T} \). We say that \( t \) is weakly normalizing if there is at least one normal form in \( G_\mathcal{T}(t) \) and that \( t \) is strongly normalizing if \( G_\mathcal{T}(t) \) is finite and acyclic. When all the \( \mathcal{E} \)-terms are strongly normalizing, \( \mathcal{T} \) is terminating. Besides, if for any \( t, s_1, s_2 \in \mathcal{T}(\mathcal{E}) \), \( t \preceq s_1 \) and \( t \preceq s_2 \) implies the existence of \( t' \in \mathcal{T}(\mathcal{E}) \) such that \( s_1 \preceq t' \) and \( s_2 \preceq t' \), then \( \mathcal{T} \) is confluent.

1.1.5. Partial orders. When \( \mathcal{T} := (\mathcal{E}, \rightarrow) \) is an ATRS such that \( \preceq \) is antisymmetric, \( \preceq \) is a partial order relation. In this case, \( \mathcal{T} \) has the poset property and we shall denote by \( P_\mathcal{T} \) the poset \( (\mathcal{T}(\mathcal{E}), \preceq) \). For any \( t \in \mathcal{T}(\mathcal{E}) \), let \( P_\mathcal{T}(t) \) be the subposet of \( P_\mathcal{T} \) having \( t \) as least element. Again in this case, a \( \mathcal{E} \)-term \( t \) is minimal (resp. maximal) if \( t \) is a minimal (resp. maximal) element of \( P_\mathcal{T} \). Observe that any normal form is maximal but the converse is false because a maximal element \( t \) could satisfy \( t \Rightarrow t \). A \( \mathcal{E} \)-term \( t \) is isolated if \( t \) is both minimal and maximal.

When \( \mathcal{T} \) has the poset property, \( \mathcal{T} \) is rooted if for any term \( t \), the subposet \([t]_\equiv \) of \( P_\mathcal{T} \) has a unique minimal element. Finally, \( \mathcal{T} \) has the lattice property if \( \mathcal{T} \) has the poset property and for all \( t \in \mathcal{T}(\mathcal{E}) \), all posets \( P_\mathcal{T}(t) \) are lattices.

1.2. Combinatory logic systems. We begin by defining combinatory logic systems as particular ATRS and present some consequence of nonerasing and hierarchical combinatory logic systems (notions defined thereafter). We explain some of the consequences of the local finiteness, the poset property, and the lattice property on the models of combinatory logic systems.

1.2.1. Main definitions. A combinatory logic system (or CLS for short) is an ATRS \( \mathcal{G} := (\mathcal{E}, \rightarrow) \) such that for each constant \( X \) of \( \mathcal{E} \), there is exactly one rewrite rule where \( X \) appears, and this rule is of the form

\[
X x_1 \ldots x_n \rightarrow t_X
\]  

(1.2.1)

where \( n \geq 1 \) and \( t_X \) is a term having no constants and having all variables in \( X_n \). Moreover, all rewrite rules of \( \mathcal{G} \) must be of the form (1.2.1). The integer \( n \) is the order of \( X \) in \( \mathcal{G} \). Some well-known terms \( t_X \) appearing among others in [Smu85] are,

- with order 1, \( t_1 := x_1 \) (Identity bird), \( t_{\text{LM}} := x_1 x_1 \) (Mockingbird);
- with order 2, \( t_K := x_1 \) (Kestrel), \( t_T := x_2 x_1 \) (Thrush), \( t_{\text{LM}} := x_1 x_1 x_2 \) (Mockingbird 1), \( t_W := x_1 x_1 x_2 \) (Warbler), \( t_L := x_1(x_2 x_2) \) (Lark), \( t_O := x_2(x_1 x_2) \) (Owl), \( t_U := x_2 x_1 x_1 x_2 \) (Turing Bird);
• with order 3, \( t_C := x_1x_3x_2 \) (Cardinal), \( t_V := x_3x_1x_2 \) (Vireo), \( t_B := x_1(x_2x_3) \) (Bluebird),
\( t_S := x_1x_3(x_2x_3) \) (Starling);

• with order 4, \( t_J := x_1x_2(x_1x_4x_3) \) (Jay).

The constant \( X \) is nonerasing if \( t_X \) contains at least one occurrence of each variable \( x_i \) for any \( i \in [n] \). The constant \( X \) is hierarchical if for any \( i \in [n] \), \( x_i \) appears in \( t_X \) at depth \( n + 1 - i \). For instance, the terms \( t_X \) such that \( X \) are hierarchical and of order 3 or less are

\[
x_1x_1, \ x_1x_1x_2, \ x_2(x_1x_1), \ x_1x_1x_2x_3, \ x_2(x_1x_1)x_3, \ x_3(x_1x_1x_2), \ x_3(x_2(x_1x_1)).
\]

In particular, if \( X \) is hierarchical, then \( X \) is nonerasing. We say that \( G \) is nonerasing (resp. hierarchical) if all constants of \( G \) are nonerasing (resp. hierarchical). Other interesting properties of basic combinators are introduced in [Bim11] but they do not intervene directly in this work.

Consider for instance the CLS \( G := (\emptyset, \to) \) where \( \emptyset \) contains only the constant \( I \) where \( t_I \) is defined above. It is straightforward to show that \( G \) has the poset property. Nevertheless, \( G \) has not the lattice property, as suggested by the Hasse diagram shown in Figure 1a. On the other side, the CLS \( G := (\emptyset, \to) \) where \( \emptyset \) contains only the constants \( K \) and \( S \) where \( t_K \) and \( t_S \) are defined above does not have the poset property. Indeed, \( \preceq \) is not antisymmetric because by setting \( t := S(S(KS)(K(SKK))(K(SKK))) \), we have \( s \preceq s' \) and \( s' \preceq s \) where \( s := \text{ttf}(tt) \) and \( s' := \text{ttf}(ttt) \). This can be seen by noticing that \( tx_1x_2 \preceq x_2x_2 \). Figure 1b shows a part of the rewrite graph of \( G \).

1.2.2. Properties of CLS. Let us state some properties of CLS related to their properties of confluence, termination, and local finiteness.

**Proposition 1.2.1.** Any CLS is confluent.

**Proof.** By definition, the underlying ATRS of any CLS is orthogonal [BN98, Chapter 6]. The statement follows from the fact that all orthogonal rewrite systems are confluent [Ros73].
Lemma 1.2.2. Let $\mathcal{G} := (\mathfrak{G}, \rightarrow)$ be a CLS. If $\mathcal{G}$ is nonerasing, then for any $n \geq 0$ and $t \in \mathfrak{T}_n(\mathfrak{G})$, $[t]_n \subseteq \mathfrak{T}_n(\mathfrak{G})$.

Proof. Assume that $t$ and $t'$ are two $\mathfrak{G}$-terms such that $t \implies t'$. From the definition of $\implies$ from $\rightarrow$ provided by (1.1.7), the fact that all constants of $\mathfrak{G}$ are nonerasing implies that for any $x_i \in X$, $\deg_{x_i}(t) \geq 1$ if and only if $\deg_{x_i}(t') \geq 1$. Therefore, both $t$ and $t'$ belong to $\mathfrak{T}_n(\mathfrak{G})$ where $n$ is an integer nonsmaller than the greatest index of the variables appearing in $t$ and $t'$. Since $\equiv$ is the reflexive, symmetric, and transitive closure of $\implies$, the result follows.

Proposition 1.2.3. Let $\mathcal{G} := (\mathfrak{G}, \rightarrow)$ be a CLS. If $\mathcal{G}$ is hierarchical, then $\mathcal{G}$ is locally finite and all the $\equiv$-terms of a same connected component of $G_\mathcal{G}$ have the same height.

Proof. Assume that $t$ and $t'$ are two $\mathfrak{G}$-terms such that $t \implies t'$. From the definition of $\implies$ from $\rightarrow$ provided by (1.1.7), the fact that all constants of $\mathfrak{G}$ are hierarchical implies that $ht(t) = ht(t')$. Moreover, since $\mathcal{G}$ is also nonerasing, by Lemma 1.2.2, for any $x_i \in X$, $\deg_{x_i}(t) \geq 1$ if and only if $\deg_{x_i}(t') \geq 1$. Observe moreover that for any $n \geq 0$, the number of terms of the same height in $\mathfrak{T}_n(\mathfrak{G})$ is finite. Since $\equiv$ is the reflexive, symmetric, and transitive closure of $\implies$, and since two terms $t$ and $t'$ are $\equiv$-equivalent if and only if $t$ and $t'$ belong to the same connected component of $G(\mathcal{G})$, the result follows.

Let us use these results to state some properties of a CLS $\mathcal{G}$. By Proposition 1.2.1 and [BKdVT03, Theorem 1.2.2], each $\equiv$-equivalence class of terms of $\mathcal{G}$ admits at most one normal form. If $\mathcal{G}$ is hierarchical and has the poset property, it follows by Proposition 1.2.3 that for each term $t$ of $\mathcal{G}$, the subposet on $[t]_n$ of $\mathcal{P}_\mathcal{G}$ admits exactly one maximal element. If additionally $\mathcal{G}$ is rooted, then for each term of $\mathcal{G}$, the subposet on $[t]_n$ of $\mathcal{P}_\mathcal{G}$ admits exactly one minimal element. In this case, there is a one-to-one correspondence between the set of the minimal terms and the set of the maximal terms of $\mathcal{G}$ and this correspondence preserves the $\equiv$-equivalence classes.

1.2.3. Models. Let $\mathcal{G} := (\mathfrak{G}, \rightarrow)$ be a CLS. A model of $\mathcal{G}$ is an algebra over the abstract clone defined as the quotient of $\mathfrak{T}(\mathfrak{G})$ by the clone congruence $\equiv$ (see for instance [Tay95] for a general description of algebras over abstract clones). In more concrete terms, for this particular case of abstract clone, this is the data of a magma $(M, \cdot)$ such that $\mathfrak{G} \subseteq M$ and, for each rule $X_1 \ldots X_n \rightarrow t_X$, the axiom $(\ldots ((X \cdot x_1) \cdot x_2) \ldots) \cdot x_n = e_X$ holds, where $e_X$ is the expression having $t_X$ as syntax tree. For instance, a model of the CLS on the constants $K$ and $S$ is a set $M$ containing $K$ and $S$, and endowed with an operation $\ast : M^2 \rightarrow M$ satisfying $(K \cdot x_1) \ast x_2 = x_1$ and $((S \cdot x_1) \ast x_2) \ast x_3 = (x_1 \ast x_3) \ast (x_2 \ast x_3)$. Such structures are known as combinatory algebras [HS03].

The trivial model of $\mathcal{G}$ is the magma $(M, \cdot)$ where $M$ is the set $\mathfrak{T}(\mathfrak{G})/\equiv$ and, for any $[t_1]_n, [t_2]_n \in M$, $[t_1]_n \ast [t_2]_n$ is the $\equiv$-equivalence class of $t_1 t_2$ where $t_1$ is any element of $[t_1]_n$ and $t_2$ is any element of $[t_2]_n$. Moreover, when $\mathcal{G}$ is nonerasing, for any $n \geq 0$, the $n$-trivial model of $\mathcal{G}$ is the trivial model restrained to $\equiv$-equivalence classes of terms of $\mathfrak{T}_n(\mathfrak{G})$. Thanks to Lemma 1.2.2, the $n$-trivial model is well-defined.

When $\mathcal{G}$ is hierarchical and has the poset property, as already noticed, each $\equiv$-equivalence class contains exactly one maximal element. Therefore, the set $M^\text{max}$ of the maximal terms of $\mathfrak{T}(\mathfrak{G})$ is a set of representatives of the set of the $\equiv$-equivalence classes and forms a model of $\mathcal{G}$ isomorphic to the trivial model. When additionally $\mathcal{G}$ is rooted, as already noticed, each
§ First properties

The Mockingbird lattice

S. Giraudo

≡-equivalence class contains exactly one minimal element. For this reason, the set \( M_{\min} \) of the minimal terms of \( \mathcal{T}(\emptyset) \) is a set of representatives of the set of the \( \equiv \)-equivalence classes and forms a model of \( \mathcal{G} \) isomorphic to the previous ones. Here also, for any \( n \geq 0 \), we define the model \( M_n^{\max} \) (resp. \( M_n^{\min} \)) as the restriction of \( M_n^{\max} \) (resp. \( M_n^{\min} \)) on \( \mathcal{T}_n(\emptyset) \). The interest of these two models \( M_n^{\max} \) and \( M_n^{\min} \) relies on considerations about algorithmic complexity for the computation of the product \( t_1 \star t_2 \) where \( t_1 \) and \( t_2 \) are two terms of the models.

2. The Mockingbird lattice

This central section of this work concerns the study of the poset associated with the CLS containing the basic combinator \( M \). We shall prove that this CLS has the poset property, is rooted, and has also the lattice property by introducing new lattices on some kind of treelike structures, called duplicative forests.

2.1. The combinator \( M \) and its poset.

Let the CLS \( \mathcal{G} := (\mathcal{G}, \rightarrow) \) such that \( \mathcal{G} := \{M\} \) and \( t_M = x_1x_1 \). Since \( M \) is the Mockingbird basic combinator, we call \( \mathcal{G} \) the Mockingbird CLS. Observe that \( M \) is hierarchical so that \( \mathcal{G} \) satisfies the properties stated by Proposition 1.2.3 and is in particular locally finite. From now, we shall simply write \( G \) instead of \( G_\mathcal{G} \). Figure 2 provides an example of a fragment of \( G \).

![Figure 2. The fragment of the rewrite graph of \( \mathcal{G} \) restrained to the terms reachable from closed terms of degrees 3 or less.](image)

2.1.1. First properties. Let us present some first properties of \( \mathcal{G} \). We begin by providing a recursive description of the rewrite relation \( \Rightarrow \).

**Lemma 2.1.1.** For any \( t, t' \in \mathcal{T}(\emptyset) \), we have \( t \Rightarrow t' \) if and only if \( t = t_1t_2 \), \( t' = t'_1t'_2 \) with \( t_1, t_2, t'_1, t'_2 \in \mathcal{T}(\emptyset) \), and at least one of the following assertions holds:

(i) \( t_1 \Rightarrow t'_1 \) and \( t_2 = t'_2 \);

(ii) \( t_2 \Rightarrow t'_2 \) and \( t_1 = t'_1 \);

(iii) \( t_1 = M \) and \( t_2 = t'_1 = t'_2 \).
Proof. This is a direct consequence of the definitions of the context closure \( \Rightarrow \) from the rewrite relation \( \rightarrow \) and of the term \( t_M \). \( \square \)

**Proposition 2.1.2.** The \( \text{CLS} \) \( G \)

(i) is locally finite;

(ii) has the poset property;

(iii) is rooted.

**Proof.** First, since \( M \) is hierarchical, by Proposition 1.2.3, \( G \) is locally finite. Therefore, (i) holds.

Let us prove that \( G \) has the poset property. For this, let \( \theta : \Sigma(\mathcal{G}) \rightarrow \mathbb{Z}^2 \) be the map defined for any \( t \in \Sigma(\mathcal{G}) \) by \( \theta(t) := (\deg(t), -\deg_M(t)) \). We denote by \( \leq \) the lexicographic order on \( \mathbb{Z}^2 \) and by \( + \) the pointwise addition on \( \mathbb{Z}^2 \). Let us prove by structural induction on \( \Sigma(\mathcal{G}) \) that for any \( \mathcal{G} \)-terms \( t \) and \( t' \), \( t \neq t' \) and \( t \Rightarrow t' \) implies \( \theta(t) < \theta(t') \). By Lemma 2.1.1, we have \( t = t_1t_2 \) and \( t' = t_1't_2' \) for some \( \mathcal{G} \)-terms \( t_1, t_2, t_1', t_2' \) and we have the three following cases. First, if \( t_1 \Rightarrow t_1' \) and \( t_2 = t_2' \), then \( \theta(t) = \theta(t_1)+\theta(t_2)+(1,0) \) and \( \theta(t') = \theta(t_1')+\theta(t_2)+(1,0) \). Since, by induction hypothesis, \( \theta(t_1) < \theta(t_1') \), we have \( \theta(t) < \theta(t') \). Second, if \( t_2 \Rightarrow t_2' \) and \( t_1 = t_1' \), the same arguments as the previous ones (by interchanging the indices 1 and 2 in the concerned terms) apply. Finally, if \( t_1 = t_1' = t_2 = t_2' \), then \( \theta(t) = \theta(t_2)+(1, -1) \) and \( \theta(t') = \theta(t_2')+(1,0) \). Since \( t \neq t' \), we have \( t_2 \neq t_2' \), and so that \( \theta(t) < \theta(t') \). This implies that \( \leq \) is antisymmetric, so that (ii) holds.

To prove that \( G \) is rooted, we consider the rewrite relation \( \rightarrow' \) obtained by inverting \( \rightarrow \). Thus, \( \rightarrow' \) satisfies \( x_1x_1 \rightarrow' Mx_1 \). This ATRS \( (\Sigma(\mathcal{G}), \rightarrow') \) does not admit any overlapping term (see [BKdVT03, Chapter 2]). Therefore, it is confluent. A consequence of (i), is that this ATRS has only finite \( \equiv' \)-equivalence classes. By using additionally [BKdVT03, Theorem 1.2.2], each \( \equiv' \)-equivalence class admits exactly one term \( t \) such that for any \( t' \in [t]_{\equiv'} \), \( t' \leq' t \). This implies that in \( G \), each \( \equiv' \)-equivalence class admits exactly one minimal term. Therefore, (iii) holds. \( \square \)

By Proposition 2.1.2, \( P_G \) is a well-defined poset, called Mockingbird poset. From now, we shall simply write \( P \) instead of \( P_G \). We have the following recursive description of \( \leq \).

**Lemma 2.1.3.** For any \( t, t' \in \Sigma(\mathcal{G}) \), we have \( t \leq t' \) if and only if at least one of the following assertions holds:

(i) \( t = M = t' \);

(ii) \( t = x_i = t' \) for an \( x_i \in X \);

(iii) \( t = t_1t_2, t' = t_1't_2', t_1 \leq t_1', t_2 \leq t_2' \) where \( t_1, t_1', t_2, t_2' \in \Sigma(\mathcal{G}) \);

(iv) \( t = Mt_2, t' = t_1't_2', t_2 \leq t_2' \) and \( t_1 \leq t_1' \) where \( t_1, t_1', t_2, t_2' \in \Sigma(\mathcal{G}) \).

**Proof.** This is a direct consequence of Lemma 2.1.1 and of the fact that \( \leq \) is the reflexive and transitive closure of \( \Rightarrow \). \( \square \)

**Proposition 2.1.4.** Let \( t \in \Sigma(\mathcal{G}) \).

(i) The term \( t \) is a maximal element of \( P \) if and only if \( t \) avoids \( M(x_1x_2) \) and suffix-avoids \( Mx_1 \).

(ii) The term \( t \) is a minimal element of \( P \) if and only if \( t \) avoids \( (x_1x_2)(x_1x_2) \) and suffix-avoids \( x_1x_1 \).
§ A poset on duplicative forests

The Mockingbird lattice

S. Giraudo

Proof. The term $t$ is maximal in $\mathcal{P}$ if and only if $t \Rightarrow t'$ implies that $t' = t$. By Lemma 2.1.1, this is equivalent to the fact $t$ is maximal in $\mathcal{P}$ if and only if when $t$ has an internal node having $M$ as left subtree, this internal node admits necessarily $M$ as right subtree. Therefore, (i) holds.

The term $t$ is minimal in $\mathcal{P}$ if and only if $t' \Rightarrow t$ implies that $t' = t$. By Lemma 2.1.1, this is equivalent to the fact $t$ is minimal in $\mathcal{P}$ if and only if when $t$ has an internal node such that its two children are equal, these two children are necessarily equal to $M$. Therefore, (ii) holds.

2.1.2. Some models. We begin this discussion about models of $\mathcal{G}$ by a very simple observation: any idempotent monoid $(\mathcal{M}, \cdot, e)$ is a model of $\mathcal{G}$. Indeed, by identifying $M$ with $e$ (the unit of $\mathcal{M}$) and by identifying $\ast$ with $\cdot$, we have for any $x \in \mathcal{M}$, $M \ast x = e \cdot x = x \cdot x = x \ast x$.

Besides, since $\mathcal{G}$ is hierarchical and has, by Proposition 2.1.2, the poset property, this CLS admits the model $\mathcal{M}^{\text{max}}$ described in Section 1.2.3. More specifically, this model is such that $\mathcal{M}^{\text{max}}$ is the set of the maximal elements of $\mathcal{P}$, and, by Proposition 2.1.4, for any $t_1, t_2 \in \mathcal{M}^{\text{max}}$,

$$t_1 \ast t_2 = \begin{cases} t_2 t_1 & \text{if } t_1 = M, \\ t_1 t_2 & \text{otherwise}. \end{cases}$$

(2.1.1)

Since by Proposition 2.1.2, $\mathcal{G}$ is also rooted, $\mathcal{G}$ admits the model $\mathcal{M}^{\text{min}}$ described in Section 1.2.3. This model is such that $\mathcal{M}^{\text{min}}$ is the set of the minimal elements of $\mathcal{P}$, and, by Proposition 2.1.4, for any $t_1, t_2 \in \mathcal{M}^{\text{min}}$,

$$t_1 \ast t_2 = \begin{cases} M t_2 & \text{if } t_1 = t_2, \\ t_1 t_2 & \text{otherwise}. \end{cases}$$

(2.1.2)

By representing $\mathcal{G}$-terms directly has binary trees, the computations in $\mathcal{M}^{\text{max}}$ have a better time complexity than in $\mathcal{M}^{\text{min}}$ because to compute $t_1 \ast t_2$ in $\mathcal{M}^{\text{min}}$, we need to decide if $t_1$ and $t_2$ are equal. Nevertheless, in return, the term $t_1 \ast t_2$ produced by a computation in $\mathcal{M}^{\text{min}}$ has a number of internal nodes equal as or smaller than the analogous computation in $\mathcal{M}^{\text{max}}$.

2.2. Duplicative lattices. We introduce here duplicative forests and a partial order relation on these objects. We show that this partial relation endow all intervals of this poset with lattice structures.

2.2.1. Duplicative forests. A duplicative tree is a planar rooted tree such that each internal node is either a black node $\bullet$ or a white node $\circ$. A duplicative forest is a word $f = f(1) \ldots f(\ell)$, $\ell \geq 0$, of duplicative trees. In particular, the empty word $e$ is the empty forest. We denote by $\mathcal{D}$ (resp. $\mathcal{D}^*$) the set of such trees (resp. forests). The height $\text{ht}(f)$ of $f$ is the number of internal nodes in a longest path following edges connecting a node to one of its child. In the sequel, we shall write expressions using some occurrences of $\sigma$; each such expression denotes the two expressions obtained by replacing simultaneously all $\sigma$ either by $\circ$ or by $\bullet$. The grafting product $\boxdot$ is the unary operation $\boxdot$ on $\mathcal{D}^*$ such that for any $f \in \mathcal{D}^*$, $\boxdot(f)$ is the duplicative tree obtained by grafting the roots of the duplicative trees of $f$ on a common root node $\boxdot$. The concatenation product $.$ is the binary operation $.$ on $\mathcal{D}^*$ such that for any $f_1, f_2 \in \mathcal{D}^*$, $f_1 . f_2$ is the duplicative forest made of the trees of $f_1$ and then of the trees of $f_2$. 
2.2.2. A poset on duplicative forests. Let $\Rightarrow$ be the binary relation on $\mathcal{D}^*$ defined recursively as follows. For any $f, f' \in \mathcal{D}^*$, we have $f \Rightarrow f'$ if $f$ and $f'$ have the same length $\ell \geq 1$ and

- either $\ell = 1$, $f = (g)$ and $f' = (g' \cdot g)$ where $g \in \mathcal{D}^*$;
- or $\ell = 1$, $f = (g)$, $f' = (g')$ where $g, g' \in \mathcal{D}^*$ and $g \Rightarrow g'$;
- or $\ell \geq 2$ and there is a $j \in [\ell]$ such that $f(j) \Rightarrow f'(j)$, and for all $i \in [\ell] \setminus \{j\}$, $f(i) = f'(i)$.

We observe that $f \Rightarrow f'$ if and only if $f'$ can be obtained from $f$ by selecting a white node of $f$, by turning it into black, and by duplicating its sequence of descendants. For instance, we have

\[
\begin{array}{c}
\text{FIGURE 3. The Hasse diagram of a maximal interval of the duplicative forest poset.}
\end{array}
\]

Observe also that in this case, there are more black nodes in $f'$ than in $f$. Hence, the reflexive and transitive closure $\ll$ of $\Rightarrow$ is antisymmetric so that $(\mathcal{D}^*, \ll)$ is a poset. We call this poset the \textit{duplicative forest poset}. For any $f \in \mathcal{D}^*$, we denote by $\mathcal{D}^*(f)$ the subposet of the duplicative forest poset on the set $\{f' \in \mathcal{D}^* : f \ll f'\}$. Figure 3 shows the Hasse diagram of the poset $\mathcal{D}^*(f)$ where $f$ is a certain duplicative forest. According to this Hasse diagram, the duplicative forest poset is not graded. We have the following recursive description of $\ll$.

\textbf{Lemma 2.2.1.} For any two duplicative forests $f$ and $f'$, we have $f \ll f'$ if and only if $f$ and $f'$ have the same length $\ell \geq 0$ and one of the following assertions holds:

(i) $\ell = 0$;

(ii) $\ell = 1$, $f = (g)$ and $f' = (g' \cdot g'')$ where $g, g', g'' \in \mathcal{D}^*$, $g \ll g'$, and $g \ll g''$;

(iii) $\ell = 1$, $f = (g)$, $f' = (g')$ where $g, g' \in \mathcal{D}^*$ and $g \ll g'$;

(iv) $\ell \geq 2$ and $f(i) \ll f'(i)$ for all $i \in [\ell]$.

\textbf{Proof.} This is a direct consequence of the definitions of $\Rightarrow$ and of $\ll$. \hfill \square

A first consequence of Lemma 2.2.1 is that for any $f, f' \in \mathcal{D}^*$, $f \ll f'$ implies $ht(f) = ht(f')$. 

2.2.3. Lattices on duplicative forests. We use in the sequel the usual notions and notations about lattices (see for instance [Sta11a]). Let \( \wedge \) and \( \vee \) be the two binary, commutative, and associative partial operations on \( \mathcal{D}^* \) defined recursively, for any \( \ell \geq 0 \), \( f_1, \ldots, f_\ell \in \mathcal{D} \), \( f_1', \ldots, f_\ell' \in \mathcal{D} \), and \( f, f', f'' \in \mathcal{D}^* \), by

\[
\begin{align*}
\left(f_1 \wedge \ldots \wedge f_\ell \wedge f_1' \wedge \ldots \wedge f_\ell' \right) & := \left( f_1 \wedge f_1' \right) \ldots \left( f_\ell \wedge f_\ell' \right), \\
\left( f_1 \wedge f_1' \right) & := \left( f \wedge f' \right), \\
\left( f_1 \wedge f_1' \right) & := \sigma \left( f_1 \wedge f_1' \wedge f'' \right)
\end{align*}
\]

and

\[
\begin{align*}
\left(f_1 \vee \ldots \vee f_\ell \vee f_1' \vee \ldots \vee f_\ell' \right) & := \left( f_1 \vee f_1' \right) \ldots \left( f_\ell \vee f_\ell' \right), \\
\left( f_1 \vee f_1' \right) & := \left( f \vee f' \right), \\
\left( f_1 \vee f_1' \right) & := \sigma \left( f_1 \vee f_1' \vee f'' \right)
\end{align*}
\]

**Proposition 2.2.2.** Given a duplicative forest \( f \), the poset \( \mathcal{D}^*(f) \) is a lattice for the operations \( \wedge \) and \( \vee \).

**Proof.** This follows by structural induction on \( f \) by establishing the fact that for any \( f', f'' \in \mathcal{D}^*(f) \), the duplicative forest \( f' \wedge f'' \) (resp. \( f' \vee f'' \)) is well-defined and is the meet (resp. the join) of \( f' \) and \( f'' \). This uses Lemma 2.2.1 in order to describe \( f' \) and \( f'' \) from \( f \) knowing that \( f \leq f' \) and \( f \leq f'' \). \( \square \)

By Proposition 2.2.2, for any \( f \in \mathcal{D}^* \), each poset \( \mathcal{D}^*(f) \) is a lattice. We call it the **duplicative forest lattice** of \( f \).

Let \( \text{pr} : \mathcal{D}^* \rightarrow \mathcal{D}^* \) be the map defined recursively, for any \( \ell \geq 0 \), \( f_1, \ldots, f_\ell \in \mathcal{D}^* \), and \( f \in \mathcal{D}^* \), by

\[
\begin{align*}
\text{pr}(f_1, \ldots, f_\ell) & := \text{pr}(f_1) \ldots \text{pr}(f_\ell), \\
\text{pr}(f_1, f_2) & := \sigma(\text{pr}(f_1)), \\
\text{pr}(f) & := \text{pr}(f).
\end{align*}
\]

The duplicative forest \( \text{pr}(f) \) is the **pruning** of \( f \). This forest has by construction no occurrence of any \( \epsilon \). For instance,

\[
\begin{array}{c}
\bullet & \circ & \circ & \circ \\
\overset{\text{pr}}{\rightarrow} & \preceq & \preceq & \preceq
\end{array}
\]

**Lemma 2.2.3.** For any \( f \in \mathcal{D}^* \), the posets \( \mathcal{D}^*(f) \) and \( \mathcal{D}^*(\text{pr}(f)) \) are isomorphic.

**Proof.** This follows by structural induction on \( f \) by establishing the fact that \( \text{pr} \) is a one-to-one correspondence between the sets \( \mathcal{D}^*(f) \) and \( \mathcal{D}^*(\text{pr}(f)) \) and that \( \text{pr} \) is an order isomorphism. This uses Lemma 2.2.1 in order to have a recursive description of the order relation \( \preceq \). \( \square \)

For any \( d \geq 0 \), the **d-ladder** is the duplicative forest \( l_d \) defined recursively by \( l_0 := \epsilon \) and, for any \( d \geq 1 \), by \( l_d := \sigma(l_{d-1}) \). Let also

\[
\mathcal{L} := \bigcup_{d \geq 0} \mathcal{D}^*(l_d).
\]

By definition, \( \mathcal{L} \) is the set of the duplicative forests that are equal as or greater than a d-ladder for \( d \geq 0 \).
Lemma 2.2.4. For any $f \in \mathcal{D}^*$, there exists $g \in \mathcal{L}$ such that $pr(f) = pr(g)$.

Proof. This follows by structural induction on $f$ by showing that there is a $d \geq 0$ such that $l_d \ll g$ and $pr(f) = pr(g)$. This uses Lemma 2.2.1. □

An important consequence of Lemmas 2.2.3 and 2.2.4 is that for any $f \in \mathcal{D}^*$, there exists $d \geq 0$ such that $\mathcal{D}^*(f)$ is isomorphic as a poset to a maximal interval of $\mathcal{D}^*(l_d)$.

2.3. Mockingbird lattices. We show here that each subposet $\mathcal{P}(t), t \in \mathcal{T}(\mathcal{G})$, of $\mathcal{P}$ is a lattice. This is based on a poset isomorphism between $\mathcal{P}(t)$ and an interval of a lattice of duplicative forests. We also define for each $d \geq 0$ the Mockingbird lattice of order $d$ as a particular maximal interval of $\mathcal{P}$.

2.3.1. From terms to duplicative forests. Let $fr : \mathcal{T}(\mathcal{G}) \to \mathcal{D}^*$ be the map defined recursively, for any $x_i \in X$ and $t, t' \in \mathcal{T}(\mathcal{G})$, by

\begin{align}
fr(x_i) & := \epsilon, \quad \text{(2.3.1a)} \\
fr(M) & := \epsilon, \quad \text{(2.3.1b)} \\
fr(t \cdot t') & := \begin{cases} 
\circ(fr(t)) & \text{if } t = M \text{ and } t' \neq M, \\
\circ(fr(t) \cdot fr(t')) & \text{otherwise.} 
\end{cases} \quad \text{(2.3.1c)}
\end{align}

For instance,

\[ \begin{array}{c}
\text{M} \\
\text{x_1} \\
\text{M} \\
\text{x_2} \\
\text{M} \\
\end{array} \quad \xrightarrow{fr} \quad \begin{array}{c}
\text{fr} \\
\text{fr(t)} \\
\text{fr(t')} \\
\end{array} \]

Intuitively, $fr(t)$ is the duplicative forest obtained from $t$ by the following process: replace each internal node of $t$ having $M$ as left child and having a right child different from $M$ by a $\circ$, replace each other internal node of $t$ by a $\circ$, and remove all the leaves. Immediately from the definition, we observe that this map is not injective. Moreover, again directly from the definition, any duplicative forest $f$ in the image of $fr$ is such that each white node of $f$ has no more than one child.

Lemma 2.3.1. For any $t \in \mathcal{T}(\mathcal{G})$, the restriction of the map $fr$ on the domain $\mathcal{P}(t)$ is injective.

Proof. This follows by structural induction on $t$ by establishing the fact that for any $s, s' \in \mathcal{P}(t)$, $fr(s) = fr(s')$ implies $s = s'$. This uses in particular Lemma 2.1.3 in order to describe $s$ and $s'$ from $t$ knowing that $t \ll s$ and $t \ll s'$. □

Lemma 2.3.2. Let $t \in \mathcal{T}(\mathcal{G})$ and $s, s' \in \mathcal{T}(t)$ such that $s \neq s'$. We have $s \Rightarrow s'$ if and only if $fr(s) \Rightarrow fr(s')$.

Proof. This follows by structural induction on $t$. This uses in particular the definition of the binary relation $\Rightarrow$ on $\mathcal{D}^*$, Lemma 2.1.3 in order to describe $s$ and $s'$ from $t$ knowing that $t \ll s$ and $t \ll s'$, and Lemma 2.1.1 in order to describe $s'$ from $s$ knowing that $s \neq s'$ and $s \Rightarrow s'$. □
\textbf{Proposition 2.3.3.} For any $t \in \Sigma(\emptyset)$, the posets $\mathcal{P}(t)$ and $\mathcal{D}^*(fr(t))$ are isomorphic.

\textit{Proof.} Let $D := \{fr(t) : t \in \mathcal{P}(t)\}$. By Lemma 2.3.1, the sets $\mathcal{P}(t)$ and $D$ are in one-to-one correspondence. Moreover, by Lemma 2.3.2, we have that $D = \mathcal{D}^*(fr(t))$ and that $fr$ is an order isomorphism between $\mathcal{P}(t)$ and $\mathcal{D}^*(fr(t))$. \hfill \Box

Figure 4 shows the poset $\mathcal{P}(t)$ for a $\emptyset$-term $t$ and the isomorphic poset $\mathcal{D}^*(fr(t))$.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{figure4.png}
\caption{A maximal interval of the Mockingbird poset from the term $t := M(x_1(Mx_2))(MM)$ and its realization as a maximal interval in the duplicative forest poset.}
\end{figure}

\textbf{Theorem 2.3.4.} For any $t \in \Sigma(\emptyset)$, the poset $\mathcal{P}(t)$ is a finite lattice.

\textit{Proof.} By Proposition 2.3.3, $\mathcal{P}(t)$ is isomorphic as a poset to $\mathcal{D}^*(fr(t))$. Hence, and since by Proposition 2.2.2, $\mathcal{D}^*(fr(t))$ is a lattice, $\mathcal{P}(t)$ also is. The finiteness of $\mathcal{P}(t)$ is a consequence of the fact that by Proposition 2.1.2, $\emptyset$ is locally finite. \hfill \Box

The \textit{Mockingbird lattice} of order $d \geqslant 0$ is the lattice $M(d) := \mathcal{P}(t_d)$ where $t_d$ is the term recursively defined by $t_0 := M$ and, for any $d \geqslant 1$, by $t_d := M(t_{d-1})$. Figure 5 shows the Hasse diagrams of the first Mockingbird lattices.

\textbf{Theorem 2.3.5.} For any $f \in \mathcal{D}^*$, the poset $\mathcal{D}^*(f)$ is isomorphic to a maximal interval of a Mockingbird lattice.

\textit{Proof.} By Lemmas 2.2.3 and 2.2.4, the poset $\mathcal{D}^*(f)$ is isomorphic to a maximal interval of $\mathcal{D}^*(l_d)$ for a $d \geqslant 0$. Since $pr^*(fr(t_{d+1})) = l_d$ and since by Proposition 2.3.3, the poset $\mathcal{P}(t_{d+1}) = M(d+1)$ is isomorphic to $\mathcal{D}^*(l_d)$, the poset $\mathcal{D}^*(f)$ is isomorphic to a maximal interval of $M(d+1)$. \hfill \Box

Theorem 2.3.5 justifies the fact that the study of the Mockingbird lattices is universal enough because these lattices contain as maximal interval all duplicative forest lattices.

The Mockingbird lattices are not graded and not self-dual. Since they are not graded, they are not distributive neither. Moreover, they are not semidistributive. For instance, in $M(3)$, by setting $t_1 := M(MM(MM))$, $t_2 := MM(MM)(M(MM))$, and $t_3 := M(MM)(MM(MM))$, we have $t_1 \land t_2 = t_1 \land t_3$ but $t_1 \land (t_2 \lor t_3) \neq t_1 \land t_2$, contradicting one of the required relations to have this property.
3. Enumerative properties

In this last central part of this work, we present some enumerative results concerning the Mockingbird poset and lattices $M(d)$, $d \geq 0$. We enumerate the maximal and minimal elements of the Mockingbird poset by degree and by height, the length of the shortest and longest saturated chains in $M(d)$, the number of elements in $M(d)$, the number of edges in the Hasse diagram of $M(d)$, and the number of intervals of $M(d)$. All this use the lattice isomorphism between the Mockingbird lattices and the duplicative forest lattices introduced in the previous sections and formal series on terms and on duplicative forests.

3.1. Formal power series. We set here some notions about formal power series and generating series. For the rest of the text, $\mathbb{K}$ is any field of characteristic zero (as $\mathbb{Q}$ for instance).

3.1.1. Formal power series over sets. For any set $X$, let $\mathbb{K}\langle X \rangle$ be the linear span of $X$. The dual space of $\mathbb{K}\langle X \rangle$ is denoted by $\mathbb{K}\langle\langle X \rangle\rangle$ and is by definition the space of the maps $F : X \to \mathbb{K}$, called $X$-series. The coefficient $F(x)$ of any $x \in X$ is denoted by $\langle x, F \rangle$. The support of $F$ is the set $\text{Supp}(F) := \{ x \in X : \langle x, F \rangle \neq 0 \}$. The characteristic series of any subset $X'$ of $X$ is the series $c(X')$ having $X'$ as support and such that the coefficient of each $x \in X'$ is 1. For any $k \geq 0$, $T^k \mathbb{K}\langle\langle X \rangle\rangle$ is the $k$-th tensor power of $\mathbb{K}\langle\langle X \rangle\rangle$. Elements of this space are possibly infinite linear combinations of tensors $x_1 \otimes \cdots \otimes x_k$, where for any $i \in [k], x_i \in X$. The tensor algebra of $\mathbb{K}\langle\langle X \rangle\rangle$ is the space

$$T^* \mathbb{K}\langle\langle X \rangle\rangle := \bigoplus_{k \geq 0} T^k \mathbb{K}\langle\langle X \rangle\rangle. \quad (3.1.1)$$

This space is endowed with the tensor product $\otimes$ so that $(T^* \mathbb{K}\langle\langle X \rangle\rangle, \otimes)$ is a unital associative algebra, admitting 1 $\in \mathbb{K}$ as unit.

A linear map $\phi : T^{k_1} \mathbb{K}\langle\langle X \rangle\rangle \to T^{k_2} \mathbb{K}\langle\langle X \rangle\rangle$, $k_1, k_2 > 0$, is a $(k_1, k_2)$-operation on $\mathbb{K}\langle\langle X \rangle\rangle$. To lighten the notation, when $\phi$ is a $(2,1)$-operation on $\mathbb{K}\langle\langle X \rangle\rangle$, we shall sometimes use $\phi$ as an infix operation by writing $F_1 \phi F_2$ instead of $\phi(F_1 \otimes F_2)$ for any $F_1, F_2 \in \mathbb{K}\langle\langle X \rangle\rangle$. The diagonal coproduct is the $(1,2)$-operation $\Delta$ on $\mathbb{K}\langle\langle X \rangle\rangle$ satisfying $\Delta(x) = x \otimes x$ for any $x \in X$. When $X$
is endowed with an $n$-ary operation $\bullet : X^n \to X$, $n \geq 0$, for any $k \geq 0$, the \textit{k-linearization} of $\bullet$ is the $(nk, k)$-operation $\bullet^{nk}$ on $K(\langle X \rangle)$ satisfying

$$\bullet^{nk}(x_{1,1} \otimes \cdots \otimes x_{1,k} \otimes \cdots \otimes x_{n,1} \otimes \cdots \otimes x_{n,k}) = \bullet(x_{1,1}, \ldots, x_{n,1}) \otimes \cdots \otimes \bullet(x_{k,1}, \ldots, x_{n,k})$$

(3.1.2)

for any $x_{i,j} \in X$, $i \in [n]$, and $j \in [k]$. To lighten the notation, we shall write $\bullet^\otimes$ for $\bullet^{nk}$.

3.1.2. \textit{Generating series}. The space of the usual power series on the formal parameter $z$ is denoted by $K(\langle z \rangle)$. For any $F, F' \in K(\langle z \rangle)$, $F[z := F']$ is the series of $K(\langle z \rangle)$ obtained by substituting $F'$ for $z$ in $F$. The \textit{Hadamard product} is the binary operation $\boxtimes$ on $K(\langle z \rangle)$ defined linearly for any $n_1, n_2 \geq 0$ by

$$z^{n_1} \boxtimes z^{n_2} := [n_1 = n_2] z^{n_1}.$$  

(3.1.3)

The \textit{max product} is the binary operation $\uparrow$ on $K(\langle z \rangle)$ defined linearly for any $n_1, n_2 \geq 0$ by $z^{n_1} \uparrow z^{n_2} := z^\max\{n_1, n_2\}$. Observe that for any $F \in K(\langle z \rangle)$ and $n \geq 0$,

$$\langle z^n, F \uparrow F \rangle = \langle z^n, F \rangle^2 + 2\langle z^n, F \rangle \sum_{i \in [n]} \langle z^{i-1}, F \rangle.$$  

(3.1.4)

3.1.3. \textit{Formal power series and enumeration}. If $X$ is endowed with a map $\omega : X \to \mathbb{N}$, the $\omega$-\textit{enumeration map} is the partial map $e_{\omega} : T^{\ast} K(\langle X \rangle) \to K(\langle z \rangle)$ defined linearly for any $k \geq 1$ and $x_1, \ldots, x_k \in X$ by

$$e_{\omega}(x_1 \otimes \cdots \otimes x_k) := z^{\omega(x_1)} \uparrow \cdots \uparrow z^{\omega(x_k)}.$$  

(3.1.5)

For any $F \in T^{\ast} K(\langle X \rangle)$, the generating series $e_{\omega}(F)$ is the $\omega$-\textit{enumeration} of $F$.

In the sequel, we shall use the following strategy to enumerate a set $X$ w.r.t. such a map $\omega$: we shall provide a description of $c(X)$, then deduce a description of $e_{\omega}(c(X))$, and finally deduce from this a formula to compute the coefficients $\langle z^n, e_{\omega}(c(X)) \rangle$, $n \geq 0$.

3.2. \textit{Maximal, minimal, and isolated terms}. We use here series on terms and some operations on these in order to enumerate the closed maximal, closed minimal, and closed isolated elements of the poset $\mathcal{P}$ w.r.t. their degrees or their heights.

3.2.1. \textit{Series of terms and operations}. Recall that $\ast$ is the binary operation on $\mathcal{T}(\mathcal{O})$ such that for any $t_1, t_2 \in \mathcal{T}(\mathcal{O})$, $t_1 \ast t_2$ is the $\mathcal{O}$-term $t_1 t_2$ having $t_1$ as left subtree and $t_2$ as right subtree. Observe that for any $F_1, F_2 \in K(\langle \mathcal{T}(\mathcal{O}) \rangle)$,

$$e_{\deg}(F_1 \ast^{\otimes} F_2) = z e_{\deg}(F_1) e_{\deg}(F_2)$$

(3.2.1)

and

$$e_{\ht}(F_1 \ast^{\otimes} F_2) = z \left( e_{\ht}(F_1) \uparrow e_{\ht}(F_2) \right).$$

(3.2.2)

Observe also that for any $F \in K(\langle \mathcal{T}(\mathcal{O}) \rangle)$,

$$e_{\deg}(\ast^{\otimes}(\Delta(F))) = z \left[ e_{\deg}(F) \left[ z := z^2 \right] \right]$$

(3.2.3)

and

$$e_{\ht}(\ast^{\otimes}(\Delta(F))) = z e_{\ht}(F).$$

(3.2.4)
3.2.2. *Three series of terms.* In order to achieve the objectives described above, we begin by providing equations satisfied by the characteristic series $F_{\text{max}}$ of the closed maximal terms of $\mathcal{P}$, the characteristic series $F_{\text{min}}$ of the closed minimal terms of $\mathcal{P}$, and the characteristic series $F_{\text{iso}}$ of the closed isolated terms of $\mathcal{P}$.

**Proposition 3.2.1.** *The characteristic series $F_{\text{max}}$ satisfies*

$$F_{\text{max}} = M + M M + F_{\text{max}} \ast \bigodot F_{\text{max}} - M \ast \bigodot F_{\text{max}}.$$  \hspace{1cm} (3.2.5)

*Proof.* By using the description of Proposition 2.1.4 for the set $S$ of closed maximal elements of $\mathcal{P}$, we have

$$F_{\text{max}} = M + \sum_{s_1, s_2 \in S} \varphi_{s_1 s_2} - \sum_{s_3 \in S \setminus \{M\}} M \varphi_{s_3} = M + F_{\text{max}} \ast \bigodot F_{\text{max}} - M \ast \bigodot (F_{\text{max}} - M).$$  \hspace{1cm} (3.2.6)

This leads to (3.2.5). \hfill $\Box$

**Proposition 3.2.2.** *The characteristic series $F_{\text{min}}$ satisfies*

$$F_{\text{min}} = M + M M + F_{\text{min}} \ast \bigodot F_{\text{min}} - \ast \bigodot (\Delta(F_{\text{min}})).$$  \hspace{1cm} (3.2.7)

*Proof.* By using the description of Proposition 2.1.4 for the set $S$ of closed minimal elements of $\mathcal{P}$, we have

$$F_{\text{min}} = M + \sum_{s_1, s_2 \in S} \varphi_{s_1 s_2} - \sum_{s_3 \in S \setminus \{M\}} M \varphi_{s_3} = M + F_{\text{min}} \ast \bigodot F_{\text{min}} - \ast \bigodot (\Delta(F_{\text{min}} - M)).$$  \hspace{1cm} (3.2.8)

This leads to (3.2.7). \hfill $\Box$

**Proposition 3.2.3.** *The characteristic series $F_{\text{iso}}$ satisfies*

$$F_{\text{iso}} = M + 2 M M + F_{\text{iso}} \ast \bigodot F_{\text{iso}} - M \ast \bigodot F_{\text{iso}} - \ast \bigodot (\Delta(F_{\text{iso}})).$$  \hspace{1cm} (3.2.9)

*Proof.* By using the description of Proposition 2.1.4 for the set $S_1$ (resp. $S_2$) of the closed maximal (resp. minimal) elements of $\mathcal{P}$, the set of the closed isolated elements of $\mathcal{P}$ is the set $S = S_1 \cap S_2$ and we have

$$F_{\text{iso}} = M + \sum_{s_1, s_2 \in S} \varphi_{s_1 s_2} - \sum_{s_3 \in S \setminus \{M\}} M \varphi_{s_3} - \sum_{s_4 \in S \setminus \{M\}} \varphi_{s_4 s_4}$$

$$= M + F_{\text{iso}} \ast \bigodot F_{\text{iso}} - M \ast \bigodot (F_{\text{iso}} - M) - \ast \bigodot (\Delta(F_{\text{iso}} - M)).$$  \hspace{1cm} (3.2.10)

This leads to (3.2.9). \hfill $\Box$

3.2.3. *deg-enumerations.* A consequence of Proposition 3.2.1 and of (3.2.1) is that the deg-enumeration $D_{\text{max}}$ of $F_{\text{max}}$, enumerating the closed maximal elements of $\mathcal{P}$ w.r.t. their degrees, satisfies

$$D_{\text{max}} = 1 + z + zD_{\text{max}}^2 - zD_{\text{max}}.$$  \hspace{1cm} (3.2.11)

We deduce from this that the number of these terms of degree $d \geq 0$ is $d_{\text{max}}(d)$ where $d_{\text{max}}$ is the integer sequence satisfying $d_{\text{max}}(0) = d_{\text{max}}(1) = 1$ and, for any $d \geq 2$,

$$d_{\text{max}}(d) = \sum_{i \in [d-2]} d_{\text{max}}(i) d_{\text{max}}(d - 1 - i).$$  \hspace{1cm} (3.2.12)

The first numbers are

$$1, 1, 1, 2, 4, 9, 21, 51, 127, 323, 835,$$  \hspace{1cm} (3.2.13)
form Sequence A001006 of [Slo], and are Motzkin numbers.

Besides, a consequence of Proposition 3.2.2, (3.2.1), and (3.2.3) is that the deg-enumeration $D_{\min}$ of $F_{\min}$, enumerating the closed minimal elements of $\mathcal{P}$ w.r.t. their degrees, satisfies

$$D_{\min} = 1 + z + zD_{\min}^2 - z[D_{\min}[z := z^2]].$$

We deduce from this that the number of these terms of degree $d \geq 0$ is $d_{\min}(d)$ where $d_{\min}$ is the integer sequence satisfying $d_{\min}(0) = d_{\min}(1) = 1$ and, for any $d \geq 2$,

$$d_{\min}(d) = \sum_{i \in [d-1]} d_{\min}(i) d_{\min}(d - 1 - i) - [d \text{ is odd}] d_{\min} \left(\frac{d - 1}{2}\right).$$

The first numbers are

$$1, 1, 2, 4, 12, 34, 108, 344, 1136, 3796, 12920, 44442, 154596$$

and form Sequence A343663 of [Slo].

Besides, a consequence of Proposition 3.2.3, (3.2.1), and (3.2.3) is that the deg-enumeration $D_{\iso}$ of $F_{\iso}$, enumerating the closed isolated elements of $\mathcal{P}$ w.r.t. their degrees, satisfies

$$D_{\iso} = 1 + 2z + zD_{\iso}^2 - zD_{\iso} - z[D_{\iso}[z := z^2]].$$

We deduce from this that the number of these terms of degree $d \geq 0$ is $d_{\iso}(d)$ where $d_{\iso}$ is the integer sequence satisfying $d_{\iso}(0) = d_{\iso}(1) = 1$ and, for any $d \geq 2$,

$$d_{\iso}(d) = \sum_{i \in [d-2]} d_{\iso}(i) d_{\iso}(d - 1 - i) - [d \text{ is odd}] d_{\iso} \left(\frac{d - 1}{2}\right).$$

The first numbers are

$$1, 1, 1, 1, 3, 5, 13, 29, 71, 171, 427, 1067, 2709,$$

This sequence does not appear in [Slo] for the time being.

3.2.4. ht-enumerations. Due to the fact that $\mathcal{P}$ is hierarchical and, by Proposition 2.1.2, $\mathcal{P}$ is rooted, Proposition 1.2.3 implies that $\mathcal{P}$ satisfies the properties exposed at the very end of Section 1.2.2. In particular, in each $\equiv$-equivalence class of closed terms, there is exactly one closed maximal term, exactly one closed minimal term, and these terms have the same height. For this reason, the ht-enumerations of $F_{\max}$ and $F_{\min}$ are equal and enumerate also the $\equiv$-equivalence classes of closed terms w.r.t. their heights of their elements. By denoting by $H_{\min}$ the generating series, by Propositions 3.2.1 and 3.2.2, $H_{\min}$ satisfies

$$H_{\min} = 1 + z + z(H_{\min} \upharpoonright H_{\min}) - zH_{\min}.$$  

We deduce from this and (3.1.4) that the number of these $\equiv$-equivalence classes of terms of height $h \geq 0$ is $h_{\min}(h)$ where $h_{\min}$ is the integer sequence satisfying $h_{\min}(0) = h_{\min}(1) = 1$ and, for any $h \geq 2$,

$$h_{\min}(h) = h_{\min}(h - 1)^2 - h_{\min}(h - 1) + 2h_{\min}(h - 1) \sum_{i \in [h - 1]} h_{\min}(i - 1).$$

The first numbers are

$$1, 1, 2, 10, 170, 33490, 1133870930, 1285739648704587610$$

and form Sequence A063573 of [Slo].
§ Shortest and longest saturated chains

Besides, a consequence of Proposition 3.2.3, (3.2.2), and (3.2.4) is that the \( h \)-enumeration \( H_{\text{iso}} \) of \( \mathbb{F}_{\text{iso}} \), enumerating the closed isolated elements of \( \mathcal{P} \) w.r.t. their heights, satisfies

\[
H_{\text{iso}}(h) = 1 + 2z + z(h_{\text{iso}}(h) - 2zH_{\text{iso}}).
\]

(3.2.23)

We deduce from this and (3.1.4) that the number of these terms of height \( h \geq 0 \) is \( h_{\text{iso}}(h) \) where \( h_{\text{iso}} \) is the integer sequence satisfying \( h_{\text{iso}}(0) = h_{\text{iso}}(1) = 1 \) and, for any \( h \geq 2 \),

\[
h_{\text{iso}}(h) = h_{\text{iso}}(h - 1)^2 - 2h_{\text{iso}}(h - 1) + 2h_{\text{iso}}(h - 1) \sum_{i \in [h - 1]} h_{\text{iso}}(i - 1).
\]

(3.2.24)

The first numbers are

\[
1, 1, 1, 3, 21, 651, 457653, 210065930571
\]

and form Sequence A001699 of \( [\text{Slo}] \) which enumerates binary trees w.r.t. the height (but with a shift). Therefore, there is a one-to-one correspondence between the set of the closed isolated elements of \( \mathcal{P} \) of height \( h \geq 1 \) and the set of the binary trees of height \( h - 1 \).

3.3. Shortest and longest saturated chains. Let \( m_1 : \mathbb{D}^* \rightarrow \mathbb{N} \) be the statistics defined for any \( \ell \geq 0 \), \( f_1, \ldots, f_\ell \in \mathbb{D}^* \), and \( f \in \mathbb{D}^* \) by

\[
m_1(f_1 \ldots f_\ell) := 1 - \ell + \sum_{i \in [\ell]} m_1(f_i),
\]

(3.3.1a)

\[
m_1(o(f)) := m_1(f),
\]

(3.3.1b)

\[
m_1(c(f)) := 2m_1(f).
\]

(3.3.1c)

For instance, we have

\[
\begin{array}{cccccc}
2 & 2 & 6 & 2 & 2 \ \\
\end{array}
\rightarrow
\begin{array}{cccccc}
8 & 2 & 2 & 2 \ \\
\end{array}
\leftarrow
\begin{array}{cccccc}
1 & 10 \ \\
\end{array}
\]

where the integer decoration of each node refers to the image by \( m_1 \) of the duplicative tree rooted at this node.

Proposition 3.3.1. For any \( t \in T_{\text{fr}}(\mathbb{G}) \),

(i) a shortest saturated chain from \( t \) to the maximal element of \( \mathcal{P}(t) \) has length the number of \( o \) in \( \text{fr}(t) \);

(ii) a longest saturated chain from \( t \) to the maximal element of \( \mathcal{P}(t) \) has length \( m_1(\text{fr}(t)) \).

Proof. Let \( f := \text{fr}(t) \). By Proposition 2.3.3, the posets \( \mathcal{P}(t) \) and \( \mathbb{D}^*(f) \) are isomorphic. Therefore, to prove the statement, we consider the lengths of the shortest and longest saturated chains in \( \mathbb{D}^*(f) \) from \( f \) to \( g \) where \( g \) is the maximal element of \( \mathbb{D}^*(f) \).

First, immediately from the definition of \( \ll \), a shortest saturated chain from \( f \) to \( g \) consists in selecting at each step a white node that has no white nodes as descendants and turn it into black. This establishes (i).

Let us prove (ii) by structural induction on \( f \). We use there Lemma 2.2.1 in order to exhibit a longest saturated chain from \( f \) to \( g \). If \( f = f_1 \ldots f_\ell, \ell \geq 0 \), a longest saturated chain from \( f \) passes through the duplicative forest \( f_1 \ldots f_\ell \) and then passes through \( f_1 \cdot f_2 \ldots f_\ell \), \ldots, and ends at \( f_1 \cdot f_2 \ldots f_\ell = g \) where for any \( i \in [\ell] \), \( f_i \) is the greatest element of \( \mathbb{D}^*(f_i) \). By induction hypothesis, \( m_1(f_i) \) is the length of a longest saturated chain from \( f_i \) to \( f_i \). We deduce that the length of the former chain from \( f \) to \( g \) is \( 1 + \sum_{i \in [\ell]} m_1(f_i) - 1 \). Therefore,
(3.3.1a) is consistent. If \( f = \circ(f') \), \( f' \in D^* \), a longest saturated saturated chain from \( f \) to \( g \) has the same length as a longest saturated chain from \( f' \) to \( g' \) where \( g' \) is the greatest element of \( D^*(f') \). Hence, by induction hypothesis, \( ml(f) \) is consistent with (3.3.1b). If \( f = \circ(f'), \ f' \in D^* \), a longest saturated chain from \( f \) to \( g \) passes through the covering \( \circ(f', f') \) of \( f \). Therefore, by induction hypothesis and by (3.3.1b) and (3.3.1a), a longest saturated chain from \( f \) to \( g \) has length \( 1 + ml(\circ(f', f')) = 1 + 1 - 2 + 2ml(f') = 2ml(f') \), which is consistent with (3.3.1c).

By Proposition 3.3.1, for any \( d \geq 1 \), in \( M(d) \), shortest saturated chains are of length \( d \) and longest saturated chains are of length \( 2^{d-1} \).

3.4. Elements, covering pairs, and intervals. We use here series on duplicative forests and a palette of operations on these to enumerate the elements, covering pairs, and intervals of the Mockingbird lattices. We obtain for these three recursive formulas leading to expressions for the generating series of these numbers.

3.4.1. Series of duplicative forests and operations. We shall consider in the sequel the \( k \)-linearization \( \circ^k \), \( k \geq 0 \), of the concatenation product \( \circ \) of duplicative forests. Observe that for any \( F_1, F_2 \in \K(\langle D^* \rangle) \), we have in particular

\[
\text{en}_{\text{id}}(F_1 \circ F_2) = \text{en}_{\text{id}}(F_1) \uparrow \text{en}_{\text{id}}(F_2). \tag{3.4.1}
\]

We shall also consider the \( k \)-linearization \( \circ^k \), \( k \geq 0 \) of the grafting product \( \circ \). Observe that for any \( F \in \K(\langle D^* \rangle) \), we have in particular

\[
\text{en}_{\text{id}}(\circ^k(F)) = z \text{en}_{\text{id}}(F). \tag{3.4.2}
\]

For any \( k \geq 1 \) and \( u \in \{\circ, \circ\}^k \), the \textit{merging product} is the \( (k + |u|_{\circ}, k) \)-operation \( mg_u \) on \( \K(\langle D^* \rangle) \) satisfying, for any \( f_1, \ldots, f_k+|u|_{\circ} \in D^* \),

\[
\text{mg}_u(f_1) = \circ(f_1), \tag{3.4.3a}
\]

\[
\text{mg}_{u'}(f_1 \circ \cdots \circ f_k) = \text{mg}_u(f_1) \otimes \text{mg}_u(f_2 \circ \cdots \circ f_k), \tag{3.4.3b}
\]

\[
\text{mg}_{\circ}(f_1 \circ f_2) = \circ(f_1, f_2), \tag{3.4.3c}
\]

\[
\text{mg}_{u'}(f_1 \circ \cdots \circ f_k) = \text{mg}_u(f_1 \circ f_2) \otimes \text{mg}_u(f_3 \circ \cdots \circ f_k), \tag{3.4.3d}
\]

where \( u' \in \{\circ, \circ\}^k \). For instance, with \( k = 3 \),

\[
\text{mg}_{\circ\circ}\left( \bigcirc \otimes \bigcirc \otimes \bigcirc \otimes \bigcirc \otimes \bigcirc \right) = \bigcirc \otimes \bigcirc \otimes \bigcirc \otimes \bigcirc \otimes \bigcirc \otimes \bigcirc. \tag{3.4.4}
\]

Intuitively, this product consists in grafting a \( \circ \) onto one forest or a \( \circ \) onto a forest and its right neighbor following the letters of \( u \). Observe that for any \( u \in \{\circ, \circ\}^* \) and \( F \in T^{k+|u|_{\circ}} \K(\langle D^* \rangle) \), we have

\[
\text{en}_{\text{id}}(\text{mg}_u(F)) = z \text{en}_{\text{id}}(F). \tag{3.4.5}
\]

Let us finally define the \textit{series of ladders} as the \( D^* \)-series

\[
\text{ld} := \sum_{h \geq 0} l_h = \varepsilon + \circ + \circ + \circ + \circ + \cdots. \tag{3.4.6}
\]

Observe that

\[
\text{ld} = \varepsilon + \circ^\bigcirc(\text{ld}). \tag{3.4.7}
\]
3.4.2. Number of elements. Let \( \text{gr} \) be the \((1,1)\)-operation on \( \mathbb{K} \langle \langle D^* \rangle \rangle \) satisfying, for any \( f \in D^* \),
\[
\text{gr}(f) = \sum_{f'} f.' \tag{3.4.8}
\]
By definition, \( \text{gr}(f) \) is the characteristic series of \( D^*(f) \) and is therefore also the formal sum of all duplicative forests \( f' \) such that \( f \ll f' \). For instance,
\[
\text{gr}(\langle\langle D^* \rangle\rangle) = \sum_{f} f'. \tag{3.4.9}
\]

**Proposition 3.4.1.** For any \( \ell \geq 0, f_1, \ldots, f_\ell \in D^* \), and \( f \in D^* \),
\[
\text{gr}(f_1 \ldots f_\ell) = \text{gr}(f_1) \ast \ldots \ast \text{gr}(f_\ell),
\]
\[
\text{gr}(\circ(f)) = \circ^\ast(\text{gr}(f)), \tag{3.4.10a}
\]
\[
\text{gr}(\triangledown(f)) = \text{gr}(f) \circ \ast(\text{gr}(f \cdot f)). \tag{3.4.10b}
\]
\[
\text{gr}(\ast(f)) = \circ^\ast(\text{gr}(f)) + \ast^\ast(\text{gr}(f \cdot f)). \tag{3.4.10c}
\]

**Proof.** This follows by structural induction on duplicative forests and is a consequence of Lemma 2.2.1 describing a necessary and sufficient condition for the fact that a duplicative forest \( f' \) belong to \( D^*(f) \) and the definitions of the operations \( \circ, \circ^\ast \), and \( \ast^\ast \) on \( D^* \)-series. \( \square \)

Observe that \( \text{gr}(\text{ld}) \) is the characteristic series of the set \( \mathcal{L}^* \) (defined in Section 2.2.3). Moreover, since for any \( h \geq 0 \), all elements of \( D^* (l_h) \) have \( h \) as height, we have
\[
\text{en}_{hl}(\text{gr}(\text{ld})) = \sum_{h \geq 0} \#D^*(l_h) z^h, \tag{3.4.11}
\]
so that \( \text{en}_{hl}(\text{gr}(\text{ld})) \) is the generating series of the cardinalities of the lattices \( D^*(l_h) \), enumerated w.r.t. \( h \geq 0 \).

**Theorem 3.4.2.** The series \( \text{gr}(\text{ld}) \) satisfies
\[
\text{gr}(\text{ld}) = e + o^\ast(\text{gr}(\text{ld})) + e^\ast(\text{gr}(\text{ld})), \tag{3.4.12}
\]

**Proof.** By (3.4.7) and by Relation (3.4.10c) of Proposition 3.4.1, we have
\[
\text{gr}(\text{ld}) = \text{gr}(e + o^\ast(\text{ld})) = e + \sum_{h \geq 0} (o^\ast(\text{gr}(l_h)) + e^\ast(\text{gr}(l_h \cdot l_h))) \tag{3.4.13}
\]
and the relation of the statement follows. \( \square \)

**Proposition 3.4.3.** The ht-enumeration \( H_{\text{gr}} \) of \( \text{gr}(\text{ld}) \) satisfies
\[
H_{\text{gr}} = 1 + zH_{\text{gr}} + z[H_{\text{gr}} \boxtimes H_{\text{gr}}]. \tag{3.4.14}
\]

**Proof.** By (3.4.1) and by Relation (3.4.10a) of Proposition 3.4.1, we have
\[
\text{en}_{ht}(\text{gr}(\ast(\Delta(l_h)))) = \sum_{h \geq 0} \text{en}_{ht}(\text{gr}(l_h \cdot l_h))
= \sum_{h \geq 0} \text{en}_{ht}(\text{gr}(l_h) \ast \ast \text{gr}(l_h))
= \sum_{h \geq 0} \text{en}_{ht}(\text{gr}(l_h)) \ast \ast \text{en}_{ht}(\text{gr}(l_h)). \tag{3.4.15}
\]
Since for any \( h \geq 0 \), all the duplicative forests appearing in \( \text{gr}(l_h) \) have \( h \) as height, the last member of (3.4.15) is equal to \( H_{\text{gr}} \boxtimes H_{\text{gr}} \). Now, by using this identity together with (3.4.2) and Theorem 3.4.2, we obtain the stated expression for \( H_{\text{gr}} \). \( \square \)
By Proposition 2.3.3, for any \(d \geq 1\), the cardinality of \(M(d)\) is 
\[
\mathbf{h}_{gr}(h) = \langle z^h, H_{gr} \rangle
\]
where \(h = d - 1\). By Proposition 3.4.3, \(\mathbf{h}_{gr}\) is the integer sequence satisfying \(\mathbf{h}_{gr}(0) = 1\) and, for any \(h \geq 1\),
\[
\mathbf{h}_{gr}(h) = \mathbf{h}_{gr}(h - 1) + \mathbf{h}_{gr}(h - 1)^2. \tag{3.4.16}
\]
The sequence of the cardinalities of \(M(d), \, d \geq 0\), starts by
\[
1, 1, 2, 6, 42, 1806, 3263442, 1065005690806, 1134237130554218444361000442 \tag{3.4.17}
\]
and forms Sequence A007018 of [Slo].

3.4.3. Number of covering pairs. Let \(\mathbf{cv}\) be the \((1, 1)\)-operation on \(K(\langle \mathcal{D}^* \rangle)\) satisfying, for any \(f \in \mathcal{D}^*\),
\[
\mathbf{cv}(f) = \sum_{f' \in \mathcal{D}^*} \mathbf{cv}(f') \tag{3.4.18}
\]
Immediately from the definition of the covering relation \(\Rightarrow\) of \(\ll\), it follows that for any \(\ell \geq 0\), \(f_1, \ldots, f_\ell \in \mathcal{D}^*\), and \(f \in \mathcal{D}^*\),
\[
\mathbf{cv}(f_1 \ldots f_\ell) = \sum_{i \in \mathbb{N}} \mathbf{cv}(f_i) \otimes \mathbf{cv}(f_{i+1} \ldots f_\ell), \tag{3.4.19a}
\]
\[
\mathbf{cv}(f) = \mathbf{cv}(f) \otimes \mathbf{cv}(f), \tag{3.4.19b}
\]
\[
\mathbf{cv}(f) = \mathbf{cv}(f) \otimes \mathbf{cv}(f) + (\mathbf{cv}(f)) \otimes (f \cdot f). \tag{3.4.19c}
\]
Let \(\mathbf{ni}\) be the \((1, 1)\)-operation on \(K(\langle \mathcal{D}^* \rangle)\) satisfying, for any \(f \in \mathcal{D}^*\),
\[
\mathbf{ni}(f) = \mathbf{cv}(\mathbf{gr}(f)). \tag{3.4.20}
\]
By a straightforward computation, we obtain
\[
\mathbf{ni}(f) = \sum_{f' \in \mathcal{D}^*(f)} \# \{f'' \in \mathcal{D}^*(f) : f'' \Rightarrow f' \} f', \tag{3.4.21}
\]
so that the coefficient of each \(f' \in \mathcal{D}^*(f)\) in \(\mathbf{ni}(f)\) is the number of duplicative forests admitting \(f'\) as covering in \(\mathcal{D}^*(f)\). For instance (see at the same time Figure 3),
\[
\mathbf{ni}(\mathbf{f}) = \mathbf{f} + \mathbf{f} + 2 \mathbf{f} + \mathbf{f} + 2 \mathbf{f} + \mathbf{f} + 2 \mathbf{f} + \mathbf{f} + 2 \mathbf{f} + \mathbf{f} + 3 \mathbf{f} + \mathbf{f} + 4 \mathbf{f}. \tag{3.4.22}
\]

**Proposition 3.4.4.** For any \(\ell \geq 0, f_1, \ldots, f_\ell \in \mathcal{D}^*\), and \(f \in \mathcal{D}^*\),
\[
\mathbf{ni}(f_1 \ldots f_\ell) = \sum_{i \in \mathbb{N}} \mathbf{gr}(f_i)f_i \otimes \mathbf{ni}(f_1 \ldots f_i) \otimes \mathbf{gr}(f_{i+1} \ldots f_\ell), \tag{3.4.23a}
\]
\[
\mathbf{ni}(\mathbf{f}) = \mathbf{f} \otimes \mathbf{ni}(\mathbf{f}), \tag{3.4.23b}
\]
\[
\mathbf{ni}(\mathbf{f}) = \mathbf{f} \otimes \mathbf{ni}(\mathbf{f}) + \mathbf{f} \otimes (\mathbf{f} \otimes (\Delta(\mathbf{gr}(\mathbf{f})))). \tag{3.4.23c}
\]
Proof. Relations (3.4.23a) and (3.4.23b) are direct consequences of Relations (3.4.19a) and (3.4.19b), and of Proposition 3.4.1. By Proposition 3.4.1 and Relations (3.4.19b) and (3.4.19c), we have

\[
\text{n}_i(f) = \text{cv}(\otimes(\text{gr}(f))) + \otimes(\text{n}_i(f))
\]

(3.4.24)

This establishes (3.4.23c). □

Observe that

\[
\text{Supp}(\text{n}_i(l)) = \mathcal{L} \setminus \{l_h : h \geq 0\}
\]

(3.4.25)

and that the coefficient of each duplicative forest \(f\) of this set is the number of duplicative forests of this same set covered by \(f\). Moreover, since for any \(h \geq 0\), all elements of \(\mathcal{L}^+(l_h)\) have \(h\) as height,

\[
\text{en}_{ht}(\text{n}_i(l)) = \sum_{h \geq 0} \sum_{f \in \mathcal{L}^+(l_h)} \#\{f' \in \mathcal{L}^+(l_h) : f' \Rightarrow f\} z^h,
\]

(3.4.26)

so that \(\text{en}_{ht}(\text{n}_i(l))\) is the generating series of the number of edges of the Hasse diagrams of the lattices \(\mathcal{L}^+(l_h)\), enumerated w.r.t. \(h \geq 0\).

Theorem 3.4.5. The series \(\text{n}_i(l)\) satisfies

\[
\text{n}_i(l) = \text{o}^{\odot}(\text{n}_i(l)) + \text{t}^{\odot}(\text{n}_i(l), (\Delta(l))) + \text{t}^{\odot}(\Delta(\text{gr}(l))).
\]

(3.4.27)

Proof. By (3.4.7) and by Relation (3.4.23c) of Proposition 3.4.4, we have

\[
\text{n}_i(l) = \text{n}_i(\varepsilon + \text{t}^{\odot}(l))
\]

(3.4.28)

\[
= 0 + \sum_{h \geq 0} \text{n}_i(l_h)
\]

(3.4.29)

\[
= \sum_{h \geq 0} \left(\text{o}^{\odot}(\text{n}_i(l_h)) + \text{t}^{\odot}(\text{n}_i(l_h)) + \text{t}^{\odot}(\Delta(\text{gr}(l)))\right)
\]

and the relation of the statement follows. □

Proposition 3.4.6. The ht-enumeration \(H_{ni}\) of \(\text{n}_i(l)\) satisfies

\[
H_{ni} = zH_{ni} + zH_{gr} + 2z(H_{ni} \boxtimes H_{gr}).
\]

(3.4.30)

Proof. Observe first that we have

\[
\text{en}_{ht}(\Delta(\text{gr}(l))) = \sum_{h \geq 0} \sum_{f \in \mathcal{L}^+(l_h)} \text{en}_{ht}(f, f)
\]

(3.4.31)

\[
= \sum_{h \geq 0} \sum_{f \in \mathcal{L}^+(l_h)} \text{en}_{ht}(f)
\]

(3.4.32)

\[
= H_{gr}.
\]
Moreover, by (3.4.1) and by Relation (3.4.23a) of Proposition 3.4.4, we have
\[
\text{en}_{\text{hf}}(\text{ni}(\mathcal{S}(\Delta(\text{id})))) = \sum_{h \geq 0} \text{en}_{\text{hf}}(\text{ni}(h \cdot l_h))
\]
\[
= \sum_{h \geq 0} \text{en}_{\text{hf}}(\text{gr}(l_h) \otimes \text{ni}(l_h) + \text{ni}(l_h) \otimes \text{gr}(l_h))
\]
\[
= \sum_{h \geq 0} (\text{en}_{\text{hf}}(\text{gr}(l_h)) \uparrow \text{en}_{\text{hf}}(\text{ni}(l_h)) + \text{en}_{\text{hf}}(\text{ni}(l_h)) \uparrow \text{en}_{\text{hf}}(\text{gr}(l_h))).
\]
(3.4.31)

Since for any \( h \geq 0 \), all duplicative forests appearing in \( \text{gr}(l_h) \) and in \( \text{ni}(l_h) \) have \( h \) as height, the last member of (3.4.31) is equal to \( \text{H}_{\text{gr}} \otimes \text{H}_{\text{ni}} + \text{H}_{\text{ni}} \otimes \text{H}_{\text{gr}} \). Now by using this identity together with (3.4.30), (3.4.2), and Theorem 3.4.5, we obtain the stated expression for \( \text{H}_{\text{ni}} \).

By Proposition 2.3.3, for any \( d \geq 1 \), the number of edges in the Hasse diagram of \( M(d) \) is \( h_{\text{ni}}(h) := (z^h, \text{H}_{\text{ni}}) \) where \( h = d - 1 \). By Proposition 3.4.6, \( h_{\text{ni}} \) is the integer sequence satisfying \( h_{\text{ni}}(0) = 0 \) and, for any \( h \geq 1 \),
\[
h_{\text{ni}}(h) = h_{\text{ni}}(h-1) + h_{\text{gr}}(h-1) + 2h_{\text{ni}}(h-1)h_{\text{gr}}(h-1),
\]
(3.4.32)
where \( h_{\text{gr}} \) is the integer sequence defined in Section 3.4.2. The sequence of the number of edges of the Hasse diagram of \( M(d) \), \( d \geq 0 \), starts by
\[
0, 0, 1, 7, 97, 8287, 29942737, 195432804247687.
\]
(3.4.33)
This sequence does not appear in [Slo] for the time being.

3.4.4. Number of intervals. Let \( \text{ns} \) be the \((1, 1)\)-operation on \( \mathbb{K}(\langle \mathcal{D}^* \rangle) \) satisfying, for any \( f \in \mathcal{D}^* \),
\[
\text{ns}(f) = \text{gr}(\text{gr}(f)).
\]
(3.4.34)

By a straightforward computation, we obtain
\[
\text{ns}(f) = \sum_{f' \in \mathcal{D}^*(f)} \#\{ f, f' | f' \}
\]
(3.4.35)
so that the coefficient of each \( f' \in \mathcal{D}^*(f) \) in \( \text{ns}(f) \) is the number of duplicative forests smaller than or equal as \( f \) in \( \mathcal{D}^*(f) \). For instance (see at the same time Figure 3),
\[
\text{ns}(\begin{array}{c}
\circ \\
\circ \\
\end{array}) = \begin{array}{c}
\circ + 2 \circ + 2 \circ + 4 \circ + 2 \circ + 4 \circ + 3 \circ + 3 \circ \\
+ 6 \circ + 6 \circ + 6 \circ + 12 \circ \\
\end{array}.
\]
(3.4.36)

Contrary to what we have undertaken in Sections 3.4.2 and 3.4.3 where we have provided direct recursive expressions to compute \( \text{gr}(f) \) and \( \text{ni}(f) \), we fail to provide similar expressions for \( \text{ns}(f) \). The trick here consists in considering first a slightly different series depending on a parameter \( k \geq 1 \) which can be seen as a catalytic parameter. With this in mind, let for any \( k \geq 1 \), \( \text{md}_k \) be the \((1, k)\)-operation on \( \mathbb{K}(\langle \mathcal{D}^* \rangle) \) satisfying, for any \( f \in \mathcal{D}^* \),
\[
\text{md}_k(f) = \sum_{g_1 \otimes \cdots \otimes g_k, \text{ } g_1 \wedge \cdots \wedge g_k = f} g_1 \otimes \cdots \otimes g_k.
\]
(3.4.37)
where \( \wedge \) is the meet operation of the duplicative forest lattices introduced in Section 2.2.3. We call \( \text{md}_k(f) \) the \( k \)-meet decomposition of \( f \). Observe that \( \text{md}_1 \) is the identity map.
Lemma 3.4.7. For any $k \geq 1$ and $f \in D^*$,

$$\text{md}_k(\text{ns}(f)) = \sum_{f' \in D^*(f)} g_1 \otimes \cdots \otimes g_k.$$  \hfill (3.4.38)

Proof. We have

$$
\begin{align*}
\text{md}_k(\text{ns}(f)) &= \sum_{f' \in D^*(f)} \sum_{g_1, \ldots, g_k \in D^*(f')} g_1 \otimes \cdots \otimes g_k \\
&= \sum_{f' \in D^*(f)} \sum_{g_1, \ldots, g_k \in D^*(f')} \#(f, f') g_1 \otimes \cdots \otimes g_k \\
&= \sum_{g_1, \ldots, g_k \in D^*(f)} \sum_{f' \in D^*(f)} g_1 \otimes \cdots \otimes g_k,
\end{align*}
$$

showing the stated identity. \hfill \square

Proposition 3.4.8. For any $k \geq 1$, $\ell \geq 0$, $f_1, \ldots, f_\ell \in D^*$, and $f \in D^*$,

$$
\begin{align*}
\text{md}_k(\text{ns}(f_1, \ldots, f_\ell)) &= \text{md}_k(\text{ns}(f_1)) \otimes \cdots \otimes \text{md}_k(\text{ns}(f_\ell)), \quad (3.4.40a) \\
\text{md}_k(\text{ns}(\alpha(f))) &= \text{md}_k(\text{ns}(f)) \otimes \text{md}_k(\text{ns}(f)), \quad (3.4.40b) \\
\text{md}_k(\text{ns}(\emptyset(f))) &= \sum_{u \in \{\alpha, \emptyset\}^*} \text{mg}_u(\text{md}_{k+|u|}(\text{ns}(f))) + \text{md}_k(\text{ns}(f, f)), \quad (3.4.40c)
\end{align*}
$$

Proof. Relations (3.4.40a) and (3.4.40b) are direct consequences of Lemmas 2.2.1 and 3.4.7. By Lemmas 2.2.1 and 3.4.7,

$$
\begin{align*}
\text{md}_k(\text{ns}(\emptyset(f))) &= \sum_{f' \in D^*(\emptyset(f))} g_1 \otimes \cdots \otimes g_k \\
&= \sum_{\emptyset(f') \in D^*(\emptyset(f))} g_1 \otimes \cdots \otimes g_k + \sum_{\emptyset(f') \in D^*(\emptyset(f))} g_1 \otimes \cdots \otimes g_k \\
&= \sum_{f' \in D^*(\emptyset(f))} g_1 \otimes \cdots \otimes g_k + \sum_{f', f'' \in D^*(\emptyset(f))} g_1 \otimes \cdots \otimes g_k, \quad (3.4.41) \\
&= \sum_{u \in \{\alpha, \emptyset\}^*} g_1 \otimes \cdots \otimes g_k + \sum_{u \in \{\alpha, \emptyset\}^*} \emptyset(g_1 \otimes g_2) \otimes \cdots \otimes \emptyset(g_k \otimes g_k) \\
&= \sum_{u \in \{\alpha, \emptyset\}^*} \text{mg}_u(\text{md}_{k+|u|}(\text{ns}(f))) + \text{md}_k(\text{ns}(f, f)),
\end{align*}
$$

where for any duplicative forest $f$, $\text{rts}(f)$ is the word on $\{\alpha, \emptyset\}$ containing from left to right the roots of the trees forming $f$. This shows (3.4.40c). \hfill \square
Observe that \( \text{Supp}(\mathfrak{ns}(\mathfrak{ld})) = \mathcal{L} \) and that the coefficient of each duplicative forest \( f \) of this set is the number of duplicative forests of this same set smaller than or equal as \( f \). Moreover, since for any \( h \geq 0 \), all elements of \( \mathfrak{D}^*(\mathfrak{l}_h) \) have \( h \) as height,

\[
\text{en}_{ht}(\mathfrak{ns}(\mathfrak{ld})) = \sum_{h \geq 0} \sum_{\{f \in \mathfrak{D}^*(\mathfrak{l}_h)\}} \#[f, f] z^h,
\]

so that \( \text{en}_h(\mathfrak{ns}(\mathfrak{ld})) \) is the generating series of the number of intervals of the lattices \( \mathfrak{D}^*(\mathfrak{l}_h) \), enumerated w.r.t. \( h \geq 0 \).

**Theorem 3.4.9.** The series \( \mathfrak{ns}(\mathfrak{ld}) \) satisfies \( \mathfrak{ns}(\mathfrak{ld}) = \mathfrak{md}_1(\mathfrak{ns}(\mathfrak{ld})) \) where, for any \( k \geq 1 \), the series \( \mathfrak{md}_k(\mathfrak{ns}(\mathfrak{ld})) \) satisfies

\[
\mathfrak{md}_k(\mathfrak{ns}(\mathfrak{ld})) = \mathfrak{md}_k(\mathfrak{ns}(\varepsilon + \varepsilon^\circ(\mathfrak{ld})))
\]

\[
= \varepsilon \otimes \cdots \varepsilon + \sum_{u \in \mathcal{L}} \sum_{h \geq 0} \text{mg}_u(\mathfrak{md}_{k+|u|}(\mathfrak{ns}(\mathfrak{ld}))) + \varepsilon^\circ_k(\mathfrak{md}_k(\mathfrak{ns}(\varepsilon^\circ(\Delta(\mathfrak{ld})))).
\]

**Proof.** First, the relation \( \mathfrak{ns}(\mathfrak{ld}) = \mathfrak{md}_1(\mathfrak{ns}(\mathfrak{ld})) \) holds since \( \mathfrak{md}_1 \) is the identity map. By (3.4.7) and by Proposition 3.4.8, we have

\[
\mathfrak{md}_k(\mathfrak{ns}(\mathfrak{ld})) = \mathfrak{md}_k(\mathfrak{ns}(\varepsilon + \varepsilon^\circ(\mathfrak{ld})))
\]

\[
= \varepsilon \otimes \cdots \varepsilon + \sum_{u \in \mathcal{L}} \sum_{h \geq 0} \text{mg}_u(\mathfrak{md}_{k+|u|}(\mathfrak{ns}(\mathfrak{ld}))) + \varepsilon^\circ_k(\mathfrak{md}_k(\mathfrak{ns}(\varepsilon^\circ(\mathfrak{ld}))))
\]

and the relation of the statement follows. \( \square \)

**Proposition 3.4.10.** The ht-enumeration \( H_{\mathfrak{ns}} \) of \( \mathfrak{ns}(\mathfrak{ld}) \) satisfies \( H_{\mathfrak{ns}} = H_{\mathfrak{ns}} \mathfrak{H}^{(1)} \) where, for any \( k \geq 1 \), \( H_{\mathfrak{ns}} \mathfrak{H}^{(k)} \) is the ht-enumeration of \( \mathfrak{md}_k(\mathfrak{ns}(\mathfrak{ld})) \) which satisfies

\[
H_{\mathfrak{ns}}^{(k)} = 1 + z \left( H_{\mathfrak{ns}}^{(k)} \otimes H_{\mathfrak{ns}}^{(k)} \right) + z \sum_{i \in [k]} \binom{k}{i} H_{\mathfrak{ns}}^{(k+i)}.
\]

**Proof.** By Relation (3.4.40a) of Proposition 3.4.8, we have

\[
\text{en}_{ht}(\mathfrak{md}_k(\mathfrak{ns}(\varepsilon^\circ(\mathfrak{ld})))) = \sum_{h \geq 0} \text{en}_{ht}(\mathfrak{md}_k(\mathfrak{ns}(\mathfrak{l}_h)))
\]

\[
= \sum_{h \geq 0} \text{en}_{ht}(\mathfrak{md}_k(\mathfrak{ns}(\mathfrak{l}_h))) + \varepsilon^\circ_k(\mathfrak{md}_k(\mathfrak{ns}(\mathfrak{l}_h))))
\]

\[
= \sum_{h \geq 0} (\text{en}_{ht}(\mathfrak{md}_k(\mathfrak{ns}(\mathfrak{l}_h)))) + \varepsilon^\circ_k(\mathfrak{md}_k(\mathfrak{ns}(\mathfrak{l}_h))))
\]

Since for any \( h \geq 0 \), all the duplicative forests of the tensors \( \mathfrak{f}_1 \otimes \cdots \otimes \mathfrak{f}_k \) appearing in \( \mathfrak{md}_k(\mathfrak{ns}(\mathfrak{l}_h)) \) have \( h \) as height, the last member of (3.4.46) is equal to \( H_{\mathfrak{ns}}^{(k)} \otimes H_{\mathfrak{ns}}^{(k)} \). Moreover, by (3.4.5), for any \( u \in \mathcal{L} \),

\[
\text{en}_{ht}(\text{mg}_u(\mathfrak{md}_{k+|u|}(\mathfrak{ns}(\mathfrak{ld})))) = z \text{en}_{ht}(\text{mg}_{k+|u|}(\mathfrak{ns}(\mathfrak{ld}))) = z H_{\mathfrak{ns}}^{(k+|u|)}.
\]

Now, by using these two identities together with Theorem 3.4.9, and by the fact that the number of words of length \( k \) on \( \{\varepsilon, \varepsilon^\circ\} \) having exactly \( i \in [k] \) occurrences of \( \varepsilon^\circ \) is \( \binom{k}{i} \), we obtain the stated expression for \( H_{\mathfrak{ns}}^{(k)} \). Finally, we have \( H_{\mathfrak{ns}} = H_{\mathfrak{ns}} \mathfrak{H}^{(1)} \) since \( \mathfrak{ns}(\mathfrak{ld}) = \mathfrak{md}_1(\mathfrak{ns}(\mathfrak{ld})) \). \( \square \)
By Proposition 2.3.3, for any $d \geq 1$, the number of intervals in $M(d)$ is $h_{ns}^{(1)}(h) := \langle z^h, H_{ns} \rangle$ where $h = d - 1$. By Proposition 3.4.10, for any $k \geq 1$, $h_{ns}^{(k)}$ is the integer sequence satisfying $h_{ns}^{(k)}(0) = 1$ and, for any $h \geq 1$,

$$h_{ns}^{(k)}(h) = h_{ns}^{(k)}(h - 1)^2 + \sum_{i \in [k]} \binom{k}{i} h_{ns}^{(k+i)}(h - 1).$$

(3.4.48)

The sequence of the cardinalities of $M(d)$, $d \geq 0$, starts by

$$1, 1, 3, 17, 371, 144513, 20932611523, 43817662180666354657.$$  

(3.4.49)

This sequence does not appear in [Slo] for the time being.

**Open Questions and Future Work**

We have studied in this work a CLS having a lot of rich combinatorial properties despite its simplicity. This can be considered as the prototypical example for this kind of investigation. We could expect to have also similar combinatorial properties (related to poset and lattice properties, and quantitative data) for more complex CLS. In addition to the obvious possible future investigations consisting in studying in a similar fashion some other CLS, we describe here three open questions raised by this work.

The description of minimal and maximal elements of $\mathcal{P}$ uses a notion of pattern avoidance in terms (see Proposition 2.1.4). This is a general fact: when a CLS $(\mathcal{G}, \rightarrow)$ has the poset property, its minimal (resp. maximal) elements are the terms avoiding some terms deduced from the ones appearing as right-hand (resp. left-hand) members of $\rightarrow$. Such an enumerative problem has been considered in [KP15, Gir20] for the particular case of linear terms. The question here concerns the general enumeration of terms avoiding a set of other terms wherein multiple occurrences of a same variable are allowed.

We have shown that the Mockingbird CLS has the poset property and is rooted (Proposition 2.1.2), and has the lattice property (Theorem 2.3.4) by employing some specific reasoning from the definition of the Mockingbird basic combinator $M$. A question here concerns the existence of a general criterion to decide if a CLS has the poset (resp. lattice) property and if it is rooted. All this seems independent from the property of a CLS to be hierarchical because, among others, the CLS containing a basic combinator $X$ such that $X$ has order $3$ and $t_X := x_5(x_1x_3x_2)$ has not the poset property because we have $t \Rightarrow t'$ and $t' \Rightarrow t$ with $t := XX(XX(XX))$ and $t' := XX(XX)(XXX)$ while $X$ is hierarchical.

Finally, in Proposition 1.2.3, we have shown that being hierarchical is a sufficient condition for a CLS $\mathcal{G}$ to be locally finite. The question in this context consists in obtaining a necessary and sufficient condition for this last property. Observe that being nonerasing is necessary because, by assuming that $\mathcal{G}$ contains a basic combinator $X$ such that $X$ has order $n \geq 2$ and that there is $i \in [n]$ such that $x_i$ does not appear in $t_X$, we have $X x_1 \ldots x_{i-1}x_i x_{i+1} \ldots x_n \Rightarrow t_X$ for any term $s$, showing that the connected component of $t_X$ in $G_\mathcal{G}$ is infinite.
